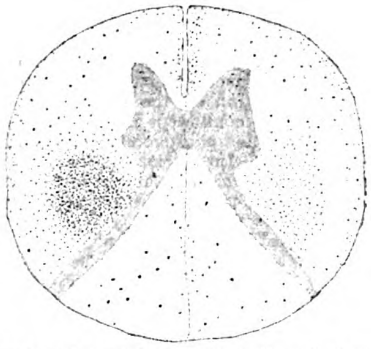
Photo-micrograph showing degenerated nerve fibre in a longitudinal section of the spinal cord ten days after experimental lesion. In places the thin axial core can be seen stained black. The greater part of it, however, is covered up by the degenerated myelin sheath, also stained black.

[1] Lectures I. and II. were published in THE LANCET of June 23rd and 30th, 1900, respectively.



[2] Exner's method is as follows. Small pieces of brain, one cubic centimetre in size, are placed in 1 per cent. of osmic acid for from five to ten days, cut in alcohol with a wet knife, after sticking on cork with shellac. The sections, which must be very thin, are mounted in glycerine. If they are allowed to remain in alcohol they spoil. They are best transferred on a section lifter in a drop of strongly ammoniated water. The preparation should be examined at once. The essential in this process is the use of the ammonia, whereby the neuro-keratin supporting structure is swollen up into a homogeneous mass. The finest fibres of the cortical layers are demonstrated remarkably well by this method.

Eichorst contend that during degeneration of the peripheral end of a cut nerve the medullary sheath and axis cylinder undergo a chemical change of such a nature that structurally and chemically it is not possible to differentiate between the two. Moreover, there are chemical reasons for supporting this view. Examination of numbers of tissues, vegetable and animal, containing, or consisting of, simple non-phosphoretted fats, by the Marchi method showed that these fatty bodies gave the black reaction. I was lead to the conclusion that probably the myelin in the process of degeneration underwent a chemical decomposition by which the complex phosphoretted fat was split up into simpler bodies—viz., glycero-phosphoric acid, stearic acid, and choline; by the taking up of water lecithin would undergo the decomposition as shown[3]:—

$$\underset{\text{lecithin,}}{C_{44}H_{90}NPO_3} + \underset{\text{water,}}{3H_2O} = \underset{\text{stearic acid,}}{2C_{18}H_{36}O_2} + \underset{\text{glycero-phosphoric acid,}}{C_3H_9PO_6} + \underset{\text{cholin.}}{C_5H_{15}NO_2}$$

To prove this I took the spinal cord from a case of right hemiplegia of 21 days' duration, the result of thrombosis of the middle cerebral artery, and divided it longitudinally into as nearly as possible equal halves, reserving a small portion for microscopical examination by the Marchi method. The two halves of the cord were dried in a sulphuric acid exsiccator and it was found that the right half lost the most in weight by this process. Both halves were then dried at 100° C. and extracted in a Soxhlet's ether apparatus

FIG. 2.

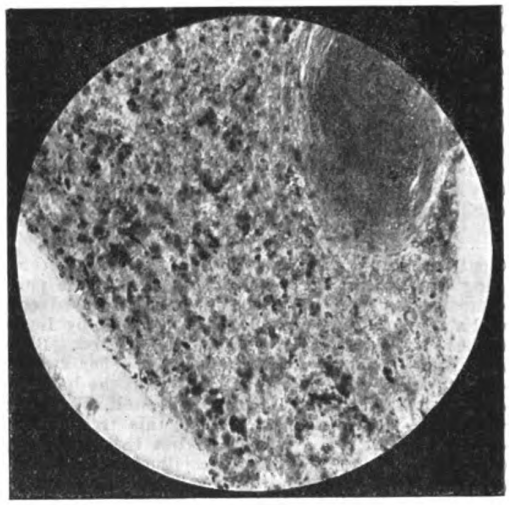
Section of first cervical segment of the spinal cord from a case of hæmorrhage into the upper part of the pons on one side, causing left hemiplegia. It will be observed that there is scattered degeneration in the homolateral pyramidal tract and also in the direct tract, but there is a very marked degeneration in the left crossed pyramidal tract. The patient died at the end of 14 days. The result of the chemical examination of the two halves of the cord is given below. Left side: ether extract, 42·1 per cent.; calculated as lecithin, 18·9 per cent.; other extractives, 23·2 per cent.; residue, 57·9 per cent.; phosphorus in ether extract, 1·72 per cent.; phosphorus in residue, 0·92 per cent.; and phosphorus in half-cord, 1·19 per cent. Right side: ether extract, 38·9 per cent.; calculated as lecithin, 22·2 per cent.; other extractives, 16·7 per cent.; residue, 61·1 per cent.; phosphorus in ether extract, 2·14 per cent.; phosphorus in residue, 0·97 per cent.; and phosphorus in half-cord, 1·38 per cent. For details of the estimation see "Archives of Neurology," p. 346.

so that all the fatty matter was extracted. It was found that on the degenerated side the ether extract appeared like butter, whereas on the non-degenerated side it was more crystalline in appearance. The degenerated right side yielded a larger proportion *pro rata* of fatty matter than the left (Fig. 2), but the phosphorus (the details of the estimation of which are given fully in the paper with Dr. J. W. Barrett) which was obtained from the right half was less than the left. The conclusion, therefore, was that the phosphoretted fat (lecithin) had broken up in the way I have mentioned; this result I have stated in my article on the Pathology of Nutrition in the first volume of Clifford Allbutt's "System of Medicine." I have since examined another cord with the same results and two others in conjunction with Dr. J. W. Barrett. The results of these examinations are given in the first volume of the *Archives of Neurology*. Some of the increase of the fat cannot, however, be accounted for by the decomposition of the lecithin; it therefore probably comes from the degeneration of the proteid of the axis-cylinder process which we have seen to give the black fat staining reaction.

THE POSSIBILITY OF DEGENERATION CAUSING AUTO-INTOXICATION.

While examining a case of acute general paralysis with numerous epileptiform seizures I was struck by the fact that the peri-vascular lymphatic sheaths of many of the vessels were filled with cells staining black like the Marchi reaction and I came to the conclusion that very probably in this disease a decomposition of the myelin of the proteid matter of the nervous system occurred incidental to the degenerative process and that the cerebro-spinal fluid, and possibly also the blood, would yield some of the products of degeneration, and perhaps the presence of such might account for some of the symptoms which occur in this disease (*vide* Fig. 3). On account of the laboratory

FIG. 3.



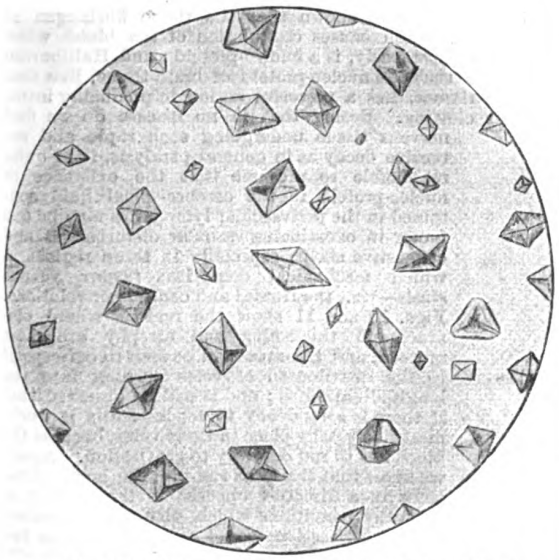


Photo-micrograph of a small vein from a case of acute general paralysis running towards the cortex with a lateral branch cut transversely, and dark in appearance on account of the contained congested blood. The section was stained by Marchi method and the whole of the external wall of the vein is seen covered with cells stained black by the fat contained in them taking up the osmic acid. Magnification 350 diameters. ("Archives of Neurology," p. 275.)

of the London County Asylums not being licensed for experiments I was fortunate enough to obtain the coöperation of my friend Professor W. D. Halliburton who was good enough to associate himself with me and conduct a series of experimental inquiries relating to this subject, a full account of which has been published in the Philosophical Transactions of the Royal Society. At first it was thought that choline only existed in the cerebro-spinal fluid and blood of patients who were suffering from general paralysis of the insane. This was no doubt due to the fact that in this disease choline was easily detected both chemically and physiologically, because in no other affection of the nervous system is there such a rapid and widespread degenerative process affecting the nervous system, but subsequent observations have shown that practically in any degenerative process affecting the nervous system if extensive enough choline can be detected in the blood, although normally it

[3] Liebreich and Diakonow considered that protagon was a mixture of lecithin and cerebrin, but numerous researches by Gamgee, Blankenhorn, Baumstark, Kossel, Freytag, and Ruppel have shown that protagon is a single chemical substance without, however, its precise constitution being determinable. Noll in an interesting paper refers to these researches and describes a method for the quantitative estimation of protagon. By this method he was enabled to show that protagon rapidly diminished in quantity in degenerating nerves and finally completely disappeared. He made comparative quantitative estimations of the two sciatic nerves after cutting the nerves on one side in dogs and horses. The protagon diminished in quantity until on the twenty-eighth day it had completely disappeared. In one case he examined the central ends of the sciatic nerves and found a considerable diminution on the side of section. He also performed an experiment relating to phosphorus, and his results, he states, are in agreement with ours with regard to the splitting up of lecithin.

does not exist in sufficient quantities to be recognisable. Thus it was found in two cases of combined sclerosis and in two cases of beri-beri where the disease had been of sufficient duration to give the Marchi reaction in the nerves; but in another case, in which the patient had died in the early stage from heart failure, there was no evidence of choline. This led to further researches and it was found that as soon as the myelin began to undergo decomposition in the peripheral portion of the experimentally cut sciatic nerves that the blood of the animals so operated upon gave the physiological and chemical reactions indicating the presence of choline. These facts show that my original surmise was true, that the protagon splits up into simpler bodies with elimination of choline. Many observers have found that extract of brain matter gave a physiological reaction similar to that of choline—namely, upon injection of a solution of an alcoholic extract of brain matter a fall in the blood-pressure was produced. This was noticed by Schäfer and Oliver, Swale Vincent, and Halliburton. The latter two have continued these researches, but arrive at somewhat different conclusions; it appears, however, to me that Halliburton is right in assuming that the effect produced is due to the existence of choline, for he finds that brain extract, like choline after injection of atropine, produces a rise instead of a fall of blood-pressure (*vide* Fig. 9). Again, the alcoholic extract of fresh brain-tissue yields the characteristic octahedral crystals which choline forms with platinum chloride (*vide* Figs. 4 and 5). In consideration of this fact we must conclude that choline is continually being formed as a normal product of lecithin metabolism and is continually escaping into the cerebro-spinal fluid which drains into the sub-arachnoid cavity and carries away the waste products of this metabolism. This view was put forward by Professor Gumprecht at the recent congress at Wiesbaden. Although it is probable that choline is continually escaping into the cerebro-spinal fluid, either it must disappear very rapidly by absorption of the fluid or it must be in very small quantities, for normal cerebro-spinal fluid did not give the physiological or chemical

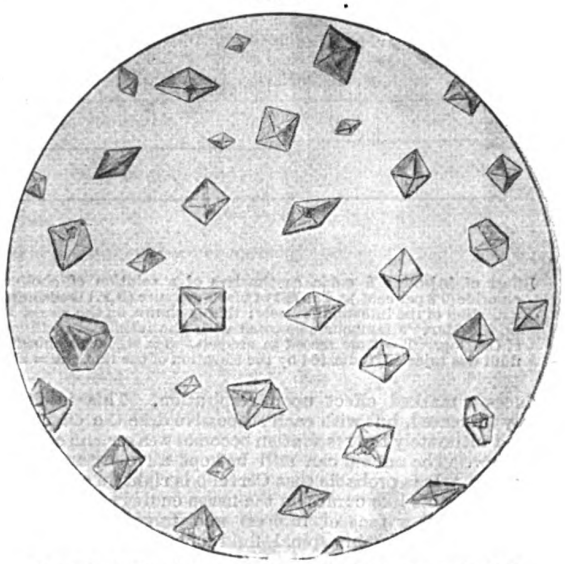

FIG. 4.

Crystals of the platinum double salt of choline crystallised from 15 per cent. alcohol.

reaction indicating the presence of choline. Gurlewitz, Schäfer, and others corroborate this statement. Hunt, in a recent paper, finds choline existing in the suprarenal gland. I have often thought it possible that one function of the suprarenal capsule, which Schäfer and Oliver in their valuable experiments proved to possess a powerful stimulating action upon the peripheral neuro-muscular mechanism of the arteries, is to produce a substance which will neutralise the influence of blood-pressure-lowering substances. Choline is not found in the urine, it is therefore probably oxidised into urea; it belongs to the same trimethylamine series of bodies as muscarine, neurine, and betaine, but it is not a powerful toxic substance, whereas neurine is. Many of the contradictory results which have been obtained as regards the toxic effects of choline are due to impure materials containing neurine having been used. Neurine, which is very much more poisonous than choline, has certain specific poisonous properties and acts especially upon the respiratory centre. In general paralysis and other diseases where a large amount of nervous tissue is undergoing degeneration choline may exist in sufficient quantities in the cerebro-spinal fluid taken from the cadaver soon after death, or even from the living subject by lumbar puncture, to give well-marked physiological and

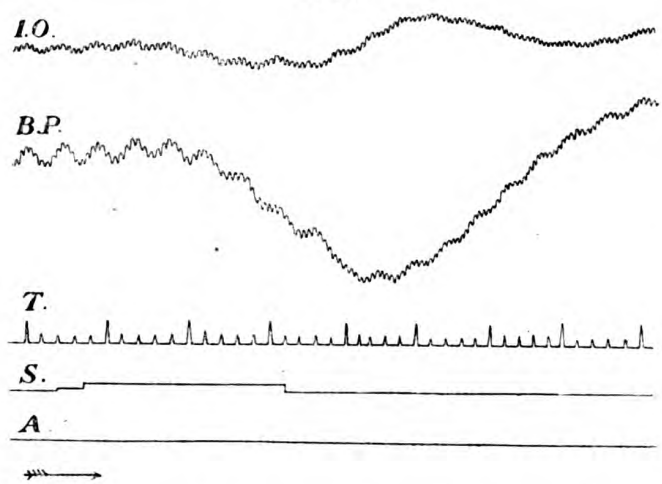

FIG. 5.

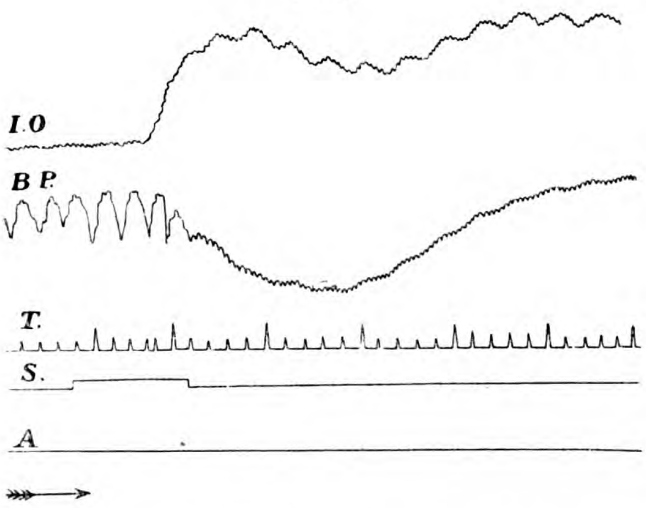
Crystals of the platinum double salt of the base separated from cerebro-spinal fluid in cases of general paralysis of the insane. Crystallised from 15 per cent. alcohol.

chemical reactions indicating its presence. Two specimens by lumbar puncture were kindly forwarded to us by Dr. J. Turner of the Essex County Asylum. It was also found in the blood taken for the purpose of treatment from patients suffering from prolonged seizures in general paralysis and from cases of beri-beri with right heart failure and asphyxia, and in the blood of other cases, such as combined sclerosis, experimental section of the sciatic nerves, &c. We may therefore assume the premiss that choline is a product of nerve degeneration, the result of breaking up of protagon or lecithin, that it escapes into the cerebro-spinal fluid, thence into the blood in larger quantities than it can be disposed of by oxidation, and that its accumulation in the blood might produce auto-intoxication. The principal physiological actions of choline were found to agree entirely with the effect produced by the intravenous injection of the cerebro-spinal fluid or the alcoholic extract of the blood (*vide* Figs. 6, 7, 8, and 9) dissolved in normal saline solution obtained from those cases. They are as follows. A fall of arterial blood-pressure, partly due to its action on the heart, but mainly due to the dilatation of the peripheral vessels, especially in the intestinal area (*vide* Figs. 6 and 7). This dilatation could actually be seen to take place through the glass lid of the intestinal oncometer when the solution was injected into the vein or if the intestine were irrigated by directly allowing the fluid to flow into the oncometer. The action on the splanchnic vessels is due to the direct action of the substance on the neuro-muscular apparatus of those vessels, for after the influence of the central nervous system has been removed by the section of the cord or of the splanchnic nerves choline still causes the typical fall of arterial pressure (*vide* Fig. 9). Neurine, a very toxic substance, we did not find in the blood or cerebro-spinal fluid, although it is possible that under certain conditions, such as the existence of micro-organisms, it might be produced. It produces upon intravenous injection first a fall, then a marked rise, and subsequently a fall of blood-pressure to the normal. Neurine

FIG. 6.



Effect of injecting 5 cubic centimetres of a solution of choline hydrochloride (0·2 per cent.). The fall of blood-pressure (B.P.) is accompanied by a dilation of the intestinal vessels; this is shown by the rise of the lever of the Marey's tambour connected with the intestinal plethysmograph (I.O.) Dog. T = time record in seconds. S = signal to show when the fluid was injected, indicated by the elevation of the line. A = abscissa.

produces a marked effect upon respiration. This is first greatly increased, but with each successive dose the effect is less and ultimately the respiration becomes weaker and ceases altogether. The animal can still be kept alive by artificial respiration. It is probable that Cervello is right in asserting that neurine acts like curare on the nerve-endings of striated muscle. Another fact of interest and importance is the existence in the cerebro-spinal fluid of a relatively large amount of proteid matter—three times as much as normal. Seeing that the cerebro-spinal fluid in the cranial cavity is greatly increased in general paralysis the quantity of proteid matter is very abundant. Examination of this proteid matter showed us that it contained a considerable amount of phosphorus; we were therefore led to believe that there was a nucleo-proteid present not found in normal cerebro-spinal fluid. As a rule we did not use the fluid itself for experimental purposes, but an alcoholic extract dissolved in saline solution, and the quantity injected (from five to ten cubic centimetres) would not contain enough nucleo-proteid to produce intravenous coagulation when diluted by the mass of blood, but in one specimen which contained a larger quantity than usual of proteid ten cubic centimetres of the cerebro-spinal fluid injected into a cat produced death by intravenous coagulation. It is therefore probable that a nucleo-proteid escaping into the cerebro-spinal fluid of the perivascular lymphatics may favour congestive stasis and even coagulation in the veins of the brain in general paralysis especially during the epileptiform seizures, when presumably the nervous tissue is undergoing disintegration. Congestive stasis in the vessels is the rule and not infrequently intravenous coagulation, and thrombosis of the large veins and even of the longitudinal sinus sometimes occurs. Thus the disintegrating nervous tissue, by providing a substance which favours stasis and coagulation, may be the means of setting up a vicious circle whereby, owing to the circulatory disturbances, acute destructive processes of the nervous tissue are brought about. This hypothesis is supported by the fact that most of the nerve-cells in the degenerating tissue of the cortex are devoid of the normal Nissl granules.

Now it has been shown by Held that these Nissl granules are the result of coagulated nucleo-albumin, for sections of nervous tissue hardened by alcohol and treated by artificial gastric juice still show the granules and these stain in a characteristic manner. Moreover, Macallum, by his modification of Lilienfeld and Monti's molybdate method, has micro-chemically demonstrated the existence of abundant phosphorus in these granules; we may therefore conclude that the disappearance of the same from the degenerating cells may be associated with the existence of a nucleo-proteid in the cerebro-spinal fluid. The researches of Halliburton have shown that the tissue fibrinogen of Wooldridge, which causes coagulation of the blood when injected intravenously, is a nucleo-proteid; and Halliburton has shown that the nucleo-proteid of brain-tissue, like that of other tissues, has a powerful action in producing intravascular clotting. Seeing that in no disease do we find nervous tissue undergoing such rapid and extensive decay as in general paralysis, it is quite reasonable to presume that the existence of nucleo-proteid in the cerebro-spinal fluid contained in the perivascular lymphatics may be one factor in occasioning vascular disturbances and congestive stasis, especially in those regions in which mechanical conditions favour venous stasis—viz., the frontal and central convolutions. Figs. 10 and 11 show the regions where pia-arachnoid thickening and atrophy are most marked, and the area will be seen to correspond to the distribution of veins opening into the longitudinal sinus; and it will be observed that if there is a tendency to venous stasis it would most likely take place in these veins, because the blood has to run contrary to gravitation. Again, we know that the veins run into the longitudinal sinus in a direction opposed to the current, so that any conditions which give rise to general venous congestion would make themselves felt especially in the area drained by these particular veins. Of course, it may be argued that the great anastomotic vein of Trollard has an important connexion with the lateral sinus and that this would prevent, in a measure, such mechanical disturbances. Still, look at it as we will, we must consider that the flow of blood in the veins I have indicated is at a mechanical disadvantage compared with that of the other veins which drain directly into the torcula or into the lateral sinus. That venous congestion does play an important part in the production of the congestive, epileptiform, and apoplectiform seizures of general paralysis is shown by the fact that a brisk purge or an enema will

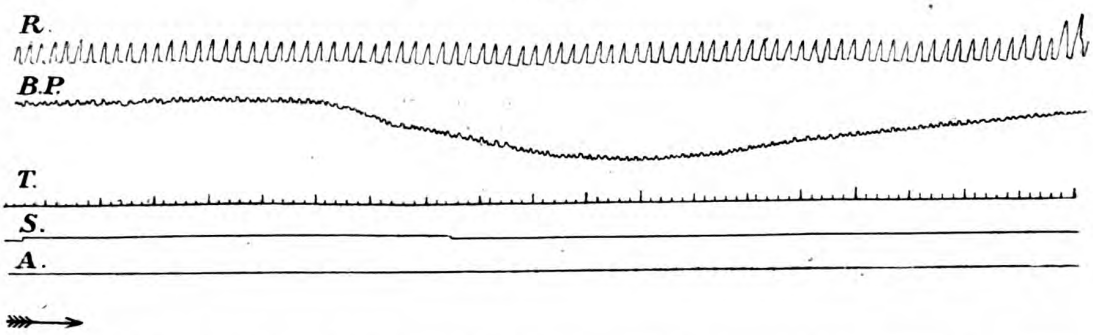


FIG. 7.

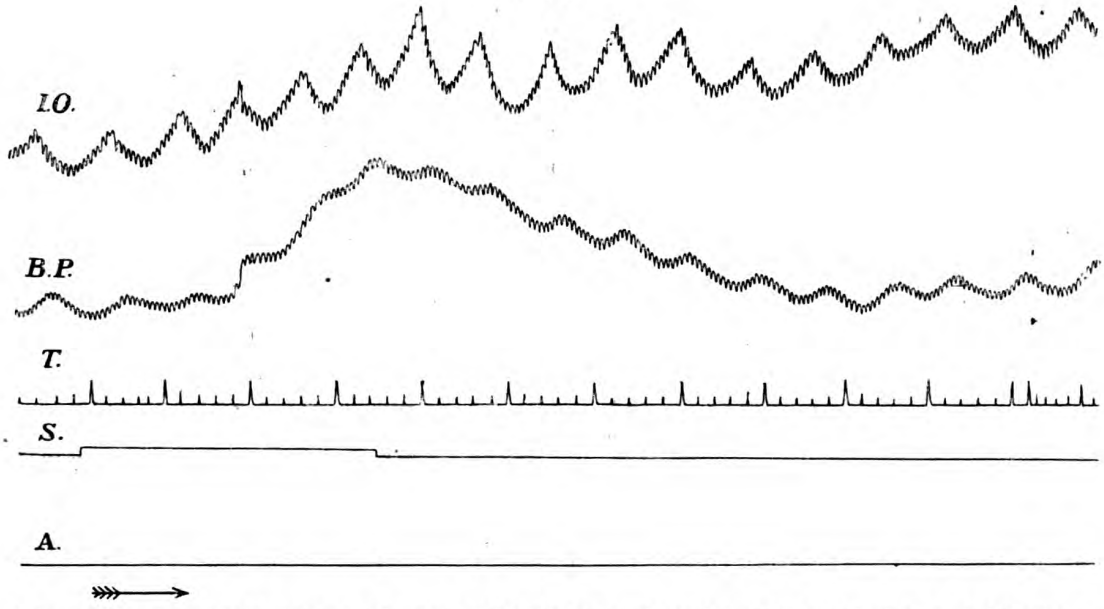
Tracing of intestinal oncometer (I.O.) and arterial blood-pressure (B.P.) in a cat. 10 cubic centimetres of cerebro-spinal fluid were injected; the same effect was obtained in the same animal by injecting 2 cubic centimetres of 0·2 per cent. solution of choline; the fall of blood-pressure is at first mainly cardiac in origin, for the oncometer tracing first follows the fall of arterial blood-pressure passively; it, however, soon rises, indicating dilatation of the peripheral vessels.

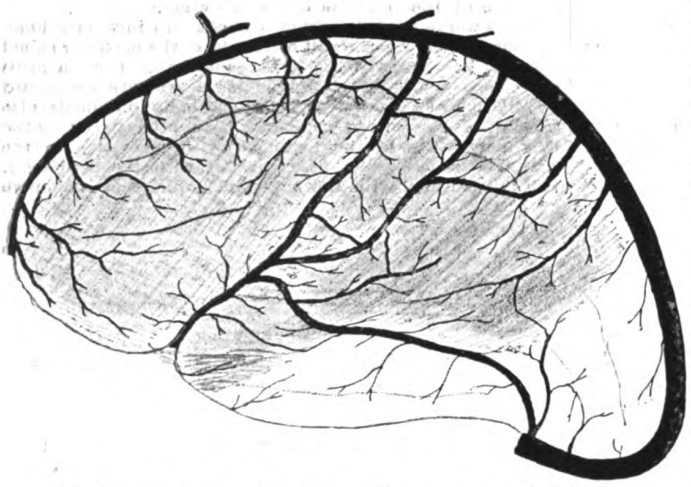


often prevent or cut short these seizures, presumably by relieving portal congestion and general venous turgescence. If, as we have seen, choline has the property of dilating the intestinal vessels in such a marked manner, it is possible to conceive that it may cause portal congestion and thus act as a factor in the production of venous stasis. The effect produced experimentally was only transitory because the quantity of choline introduced was rapidly diluted by the mass of blood, and probably oxidised also; yet when the whole mass of blood contains this substance in appreciable quantity continuously it means the possibility of constant toxic

FIG. 8.

Effect in a dog of saline solution of the alcoholic extract of 70 cubic centimetres of blood removed during a seizure from a patient suffering from general paralysis of the insane. There is no effect on respiration (R.), but there is a well-marked fall of blood-pressure (B.P.). In the same blood choline was identified chemically.

FIG. 9.



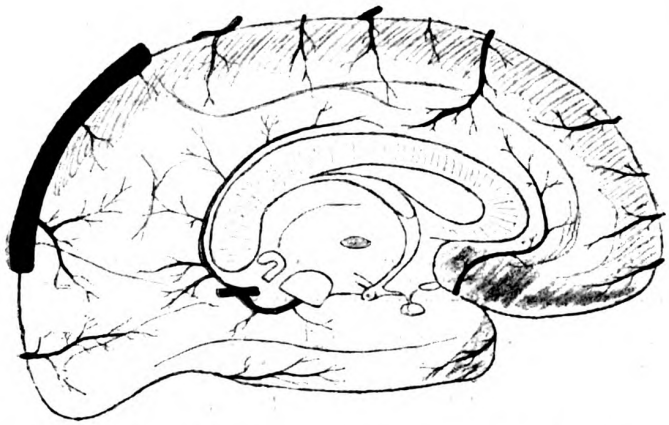
Injection of 5 cubic centimetres of pathological cerebro-spinal fluid in an animal anæsthetised with A.C.E. mixture, but which subsequently received an injection of atropine. It will be observed that now instead of producing a fall choline causes a rise of blood-pressure. The same effect is produced by the injection of 5 cubic centimetres of a 0·2 per cent. solution of choline hydrochloride.

effect; therefore, although choline can hardly be regarded as a dangerous toxic substance, still, under certain circumstances it may serve as an additional factor in the production of complications in this disease.

The Marchi reaction applied to the central and peripheral nervous systems shows rather different results; one striking difference is the comparatively rapid disappearance of the products of degeneration in peripheral nerves as compared with the central nervous system. For example, if the posterior spinal ganglia be removed and the animal kept alive for months no traces of the products of degeneration can be found in the peripheral nerves, whereas in the posterior columns of the spinal cord I have found well-marked evidence of the products of degeneration. Dr. H. Head, who has worked extensively on the changes in the cord and peripheral nerves the result of lesions of the posterior spinal ganglia, has observed the same conditions. From a large experience of this method of studying degeneration produced by all kinds of lesions of the cord and brain in animals, also from disease occurring in man, I have been struck by the long persistence of the products of degeneration in the central nervous system as compared with the peripheral. Is this connected with the anatomical difference which we know to exist between the nerve-fibres in the central nervous system and peripheral—viz., the existence in the latter of a chain of tubular cells of mesoblastic origin, forming the nucleated sheath of Schwann? And, we may ask, do these cells have a phagocytic action upon the products of degeneration, utilising the same for the formation of fresh protoplasm and myelin? and does the peripheral portion of the nerve-fibre depend solely for its nutrition upon the central cell of origin? There is some evidence in favour of the view that nerve regeneration may take place from the periphery, but there is no evidence to show that regeneration of fibres of

FIG. 10.

External and upper surface of hemisphere, showing distribution of veins opening into the longitudinal sinus. The shading shows the usual area of pia arachnoid thickening. A large branch is seen running back into the lateral sinus, connecting it with the great central anastomotic vein. The lateral sinus is diagrammatically represented as continuous with the longitudinal sinus and the torcular is not shown.



the central nervous system (where this sheath is absent) can take place.

TWO FORMS OF DEGENERATION.

There are two forms of degeneration, but both may react to the Marchi stain. They are as follows:—1. Secondary (Wallerian) degeneration due to interruption of the axon when it is cut off from its cell of origin, as, for example, in a focal transverse lesion of the spinal cord produced by disease or injury. Tracts of fibres which have their cells of origin above the lesion degenerate downwards and are recognised by the black-stained products of degeneration mapped out in definite areas corresponding to definite systems of efferent neurones, while tracts of fibres conducting afferent impulses having their cells of origin below the lesion have a normal appearance. The converse applies to tracts above the lesion—viz., all the afferent tracts which have their cells of origin below the lesion have their limits definitely mapped out by the black-stained products of degeneration, while those with their cells of origin above have a normal appearance. Therefore, secondary degenerations, whether occurring as the result of experiment or disease, may be considered of traumatic origin and arising from conditions outside the neurone very frequently due to vascular occlusion and local softening. 2. Primary degenerations are clinically and pathologically quite different from secondary. They arise as a result of altered conditions of the blood and lymph, due generally to the introduction or generation within the body of poisonous substances, and are insidious in origin, progressive in character, and generally fatal in termination. They are influenced by hereditary or acquired tendency to nervous degeneration, and election of the particular system or systems of neurones not only constitutes definite groups of clinical phenomena, which admit of empirical classification into definite diseases, but also shows that certain poisons have elective affinities for particular systems of neurones; but the election of certain structures may also be determined by occupation and habits which induce stress on some particular system of neurones, or vascular conditions may lead to circulatory disturbances which will determine the appearance of degenerative changes earlier and their more rapid progress in certain parts of the nervous system than in others. In connexion with the latter contributory factor we have already referred to the reason why certain portions of the brain should show more atrophy and degeneration in general paralysis than others. Again, I have found the left hemisphere, which presumably is used more than the right in all right-handed people, is more often atrophied in general paralysis, for the two hemispheres in this disease are seldom of equal weight, and the left hemisphere in two-thirds of these cases weighs less than the right. We know that the speech affection is one of the most characteristic and earliest clinical phenomena of this disease; possibly this difference in the weights may be the result of excessive activity of the left hemisphere while in a process of decay. At the same time, this tendency of the left hemisphere to waste more rapidly than the right might be partly explained on mechanical principles, for venous congestive stasis might take place more easily in the left hemisphere than in the right, owing to the fact that the blood in the internal jugular vein on the right side has a more direct course to the right auricle than the left.

FIG. 11.

Mesial surface of hemisphere, showing the veins opening into the longitudinal sinus draining the upper portions where the thickening of the pia arachnoid occurs. Only a small portion of the longitudinal sinus is represented. These drawings are from Testut modified to show the area of pia arachnoid thickening and its correspondence in great measure with the area drained by veins opening into the longitudinal sinus.

THE DRAINS OF FURNISHED HOUSES.—At the Devon Assizes, held on June 26th, before Mr. Justice Kennedy, a lady brought an action against a landlord for damages for breach of an implied warranty to have a house in a sanitary and habitable condition. Counsel for the plaintiff stated that she had taken a furnished house at Exeter; the agreement did not contain any stipulation as to the drains, but when a furnished house was let there was an implied warranty that it was fit for habitation. Eventually some members of the household were attacked with enteric fever and the drains were discovered to be defective. The jury awarded the plaintiff £240 damages.

AN ABSTRACT OF

The Bowman Lecture

ON

THE PRESENT STATE OF OUR KNOWLEDGE REGARDING VISUAL SENSATION.

Delivered before the Ophthalmological Society of the United Kingdom on Friday, June 15th, 1900,

BY R. MARCUS GUNN, F.R.C.S. ENG.,
SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, ETC.

MR. PRESIDENT AND GENTLEMEN,—The subject naturally demands several distinct series of observations—first, the nature of the stimulus that excites vision; secondly, the manner in which this stimulus affects sentient cells; thirdly, the path and mode of conduction of the nerve impulse; and fourthly, the ultimate appreciation of the conducted impulse.

I.—First, as to the nature of the stimulus. The expression "ether wave" must not be held necessarily to imply any actual movement in the ether, but rather an influence, a rapid, periodic change of some of its properties, the term "wave" simply meaning a disturbance of definite periodicity in space and time.

From every great centre of energy (the sun being, of course, the most important to us) radiations of energy take place, and pass through space in the form of these ether disturbances. So far as is known all such radiant energy travels at the same rate, and the "waves" occur transversely to the direction of propagation of the force. As to the nature of the vibrations or disturbances in the ether, the view now held is that first suggested by Faraday, and elaborated later by Clark-Maxwell—viz., that they are electro-magnetic. Bodies that are conductors of electricity absorb such radiations rapidly, and are therefore opaque; while those that are transparent to light are insulators. The length of the wave—that is, the interval between the disturbances—varies between many yards and four or five-millionths of an inch; that is, from the Hertzian waves on the one hand to the so-called chemical waves on the other. But all these waves, whatever their length, possess certain familiar physical properties in common; they can all be reflected, refracted, absorbed, and polarised.

The human retina is influenced by a comparatively short part of the entire scale, corresponding to what may be called an "octave"—that is, the shortest visible waves are approximately half the length of the longest—while on either side of these there are several "octaves" of invisible waves either too long or too short to be appreciated in this way. Variations in the length of the waves produce different effects on the retina of many, probably of most, animals, and these effects are instrumental in exciting in man a definite series of colour-sensations.

There is no real distinction between heat and light waves. To quote the words of the late Professor Preston: "It is not that there are two classes of waves, heat waves and light waves, but that we have two senses by which we can distinguish the same waves." The length of the wave corresponding to extreme red (32-millionths of an inch) is equivalent to about one-tenth the diameter of a red blood corpuscle, and that of violet, therefore, about one-twentieth.

II.—The phenomena produced by light in living cells of no visual function may be stated to be: (1) movement of chlorophyll corpuscles, probably associated with protoplasmic currents; (2) chemical activity produced in chlorophyll-containing cells of plants and animals; and (3) contraction of protoplasm. To these we may add (4) phototaxis, which is expressed in two ways—(*a*) the wandering of free cells towards the light and (*b*) the position assumed by the cell, parallel to the axis of the incident ray.

The earliest appearance of what can be called a visual organ is produced by a simple modification of surface epithelium; indeed, all light-sentient cells are modifications of surface epithelial cells, or developed from the same embryonic layer which forms these cells. In every class of the animal kingdom in which true eyes are to be found, examples are presented showing a high ocular development with a correspondingly high type of visual cell.

The general characteristics of such a visual cell are—(1) the end of the cell, corresponding to the cuticle, has a prolongation, usually in the form of a rod; (2) the opposite end of the cell is either directly continued as a conducting fibre, or is connected with a ganglion cell and ultimately with a nerve-fibre; and (3) pigment is present in the light-percipient cell itself, or in a distinct although closely related cell, often in both. It is to be noted that the main deposit of pigment is usually of a brown colour, and that it is situated at the end of the cuticular prolongation furthest removed from the incident light, both in invertebrates and vertebrates.

In the vertebrate retina we have, first, the pigment epithelial cell. This is of comparatively large size so that in man each cell has several end-organs embedded in it. The outer part of the cell is colourless and contains the nucleus. The remainder of the cell-body possesses much pigment, principally in the form of needles or crystals called *fuscin*. From the inner or cuticular surface of the cell arise numerous fine processes which pass inwards for a considerable distance between the end organs; they are colourless or contain pigment according to previous conditions as regards shade or exposure to light. Secondly, the neural or visual epithelial cells are, in most vertebrates, of two kinds, named, from the shape of their outer segments, rods and cones. Each cell is much elongated in a direction perpendicular to the free surface of the retina, and while its outer extremity is more or less deeply embedded in the pigment epithelium, its inner end rests on the internuclear layer. Each may be divided primarily into cell-body and cuticular formation. Under this latter term are probably to be included not only the outer segment, but also the highly refractive outer part (so-called ellipsoid) of the inner segment. The cell-body, traced from the cuticular end, begins as a distinct granular protoplasmic swelling, called the myoid; then (immediately in the case of the cone, after a varying interval in the case of the rod) comes a nucleus or granule. Next, there is a constricted part of the cell known as the fibre, and, finally, the fibre-bulb or enlargement. The relative size of rods and cones varies greatly in different vertebrates, but, where both elements exist, the chief distinctions between them consist in the greater development of the myoid in cones, and in the fact that the outer segment of the rods have, with few exceptions, a uniform reddish colour under ordinary circumstances during life.

We now come to the most important question included in this division of our inquiry—viz., what are the evidences of effect produced on such specialised light-sentient cells by the action of light? Observations on this matter have been mainly conducted on the eyes of vertebrates, and I shall confine my remarks to the effect produced on this most highly developed form of retina. First, in the pigment epithelium, when at rest, the fuscin is collected in a close mass in the body of the cell. When stimulated by light (*a*) the long pigment particles wander forwards, that is, towards the light, and invade the processes which extend between the outer segments, reaching nearly up to the external limiting membrane. This migration seems to be due to, or at any rate associated with, currents in the fluid cell-protoplasm. Marked wandering of the pigment takes place in red light, but the movement is most active towards the violet end of the spectrum and the activity seems, roughly, to be inversely proportional to the wave-length. Once the pigment is in the forward position, it returns to the body of the cell very slowly in the dark. (*b*) Also caused by exposure to light we have swelling of the pigment cell processes, which consequently grasp the outer segments. In this way the retina, over an illuminated area, is made to adhere to the pigment epithelium, forming what has been called an epithelial optogram. (*c*) Yet another effect from light is the alteration in the reaction of the contents of the pigment cell. This seems to be an oxidising process, accompanied by a substitution of an acid for a previously alkaline reaction, and there is reason to believe, from the action of staining fluids, that the change in reaction is communicated to the rods and cones, and that the activity of the chemical change varies in amount according to the wave-length.

In the visual epithelium there are several important changes brought about by exposure to light. 1. The purple of the rods undergoes change of colour wherever

the light falls on the retina, and this action is strictly confined to the illuminated area. The red end of the spectrum has but little effect, and the most active wave-lengths are those that correspond to the yellowish-green, which are the waves chiefly absorbed. Absolute bleaching ultimately takes place, the rapidity of the process depending on the intensity of the light. The purple is slowly restored in darkness if the rods remain in contact with the pigment epithelium, so that the formation of the purple stain is evidently dependent upon some action in the pigment cell, presumably of a secretory nature. 2. Movement of the cone. While a cone protrudes well into the pigment layer when protected from light, it retracts rapidly on exposure, the contraction taking place in the cone-myoid. The shorter wave-lengths act most energetically. It would seem to be an illustration of movement caused in excitable protoplasm by light. Similar but more feeble movements have been described in the rod-myoid due to the same action. 3. Photo-electrical response. It has been conclusively demonstrated that the action of light upon the retina is accompanied by a marked electrical change. The current so induced travels from pigment epithelium to nerve fibre layer, is positive in character, and is ascribed to increased disintegration. On exposing a fresh eyeball to light there is first a very short pause, followed by a rapid rise (or positive deflection); with continued illumination the positive effect increases slowly or remains stationary; and on shutting off the light there is a further short sharp rise, succeeded by a gradual fall to the position of rest. Waller has shown that there is evidence of two antagonistic processes in every such response, one positive, the other negative, the positive effect being dominant in the case of the fresh eyeball, the one possibly an evidence of disintegration, the other of reintegration. Very weak illumination—e.g., moonlight—suffices to produce the electrical variation. It has been repeatedly asserted that the electrical change depends upon the retina proper and is independent of the pigment epithelium. This, however, seems to me to require further investigation; it is difficult to believe in a marked change of this character being produced by light without the presence and participation of the pigment epithelial cells in which there is every reason to think that the light energy is mainly arrested and transformed. According to Dewar and McKendrick white light is the most effective, but on examining with spectrum colours their observations seemed to show that the yellow rays have the greatest power and that there is a gradually diminishing action on either side of the yellow. These observations on the activity of different parts of the spectrum are, however, open to the objection that the difference in response depended on the intensity rather than upon the wave-length. If the electrical change is due to the effect of light on the pigment cell we should presumably have the greatest action from that part of the spectrum that is brightest at very low intensities.

If we now compare the evidences of the effect of light on visual and on certain non-visual cells we find a striking similarity. In both there is a marked stimulation of the cell-protoplasm, combined with chemical activity, and in the case of the visual cell the amount of effect seems capable of measurement by the galvanometer. Since writing this paragraph, Dr. A. D. Waller has brought forward evidence to prove that the light effect upon a fresh leaf is also accompanied by an electrical change, thus completing in a remarkable manner the parallelism here described.

III.—The conduction of the impulse. The simplest example of the conduction of a light effect in an individual is in the case of a unicellular organism such as the *euglena*, where the whole cell responds to the influence communicated to it from without. In the neuro-muscular cells of the *hydra* the irritation is conveyed directly from the free surface to the deeply-lying processes which are in this way stimulated to contract. In the syphon of the *pholas dactylus* the superficial epithelium is pigmented and immediately beneath it there occurs a fine layer of contractile fibres which in turn overlie nerve-cells, and these again are connected with the longitudinal muscle which moves the syphon on exposure to light. Here we have an instance of a photo-chemical change in the pigment cell causing movement of the subjacent contractile tissue, serving as a mechanical irritant of the nerve-cell which occasions the general muscular movement of the syphon. This, of course, is not vision, but it is an effect, apparently purposeful, produced locally by light without any appeal to a central nerve mechanism. The effect required in lower forms of animal life—viz., escape from danger or search for food—may thus be brought about by the local effect of light. Where the body to be protected is large it is necessary to have the sense organ associated with a central nervous mechanism in order to secure protection with the minimum of specialised tissue.

We get a local combination of many light-sensory cells to form a visual apparatus and a union of many ganglion cells to form a central nervous mass. These sensory cells may be situated directly on a small collection of nerve cells, but more frequently in the case of higher forms these are connected by intermediary ganglion cells presumably formed, like the sensory cells, from epithelium, but at a later period. This explanation rests on strong biological evidence and is supported by the developmental changes which occur in the ectodermal cells forming the inner division of the secondary optic vesicle of vertebrates, where a single layer of columnar cells by multiplication is converted into three definite superimposed layers, the outermost constituting the true sensory epithelium, the innermost the large ganglion cells, and the intermediate layer the connecting bipolar ganglion cells, or inner granules. This leads us to inquire how nerve cells are connected with each other.

[The lecturer here described the modern views of the connexion between different nerve cells.]

In the present state of our knowledge as to the nature of a nerve wave it is perhaps not of great importance in attempting to follow its path to know exactly *how* the different nerve cells are brought into physiological relation with one another, so long as we are familiar with the general characteristics and position of the path traversed. The actual nature of the process associated with progress of the nerve current would appear to be most easily explained by supposing that the force, originated for example in the sensory cell, produces a physico-chemical effect on the nearest particle of the associated nerve tissue, this effect being of such a nature that it produces in turn a similar change in the state of the particle next in order, so that the influence is transmitted onwards. The influence produced locally seems to be accompanied by the formation of carbon-dioxide, and the progress of the impulse along the nerve can be traced by a change in the electrical condition known as the "current of action." The process leaves the nerve substance practically in its original condition, the nutrition of the fibre being maintained by its relation with the protoplasm of the associated ganglion cell, aided possibly in the case of long medullated axons, by the cells of the medullary sheath. In altered blood states or inflammatory conditions exhaustion readily occurs and restoration may be extremely slow or deferred indefinitely.

In the visual path, an effect having been produced on the sensory epithelial cell is immediately influential as far as the extreme termination of this cell or fibre-bulb. From this it is communicated to a bipolar ganglion cell (or inner granule) and then to one of the ganglion cells of the ganglion cell layer. Along the axis-cylinder of this cell the impulse passes as far as the external geniculate body, where this axis-cylinder ends, but the nerve wave is passed on to another neurone, the cell-body of which is in this situation, and travels along its axon to have an effect finally upon a nerve-cell of the cortex. Ramòn-y-Cajal believes that there is no direct relation, beyond that of mere contiguity, between the bulb and the outer process of the bipolar cell; that, in fact, the relation of the sensory epithelial cell to the inner granule is exactly similar to what he has described as existing between two ganglion cells elsewhere. Other observers have found distinct evidence of a direct anatomical continuity between these elements. Golgi again, and Dogiel have described a direct connexion between the ganglion and the bipolar cells.

Many rods (more than 20) and several cones may be physiologically connected respectively with single bipolar cells and several bipolar cells with one ganglion cell. This satisfactorily accounts for the relatively large number of rod and cone cells in the retina as compared with the number of fibres in the optic nerve. The cone cells of the fovea appear, however, to be exceptional, in that each has only one bipolar cell and one ganglion cell in relation with it.

What conjecture can we form with regard to the origin of the visual nerve impulse? Though the wave force which excites the retina is electrical the nerve impulse cannot be a mere continuation of it, since an electrical ether wave travels at a rate immeasurably greater than that of a nerve current. It is certain that the energy contained in the

light wave must undergo a profound change when it strikes and is arrested by the pigment, and the change that first suggests itself is that heat should be produced. But as a result of this transformed energy in the pigment chemical changes are induced, which should be compared with those brought about in plants by the action of light on chlorophyll. These chemical changes are also probably factors in the promotion of protoplasmic movement. In the case of chlorophyll the wave-lengths that are mainly arrested are the most chemically efficient, and this probably holds good also in the case of the retinal pigment.

The pigment cell when at rest has a marked secretory function, evidenced by the formation of retinal purple in the outer segments of the rods. The material thus formed is undoubtedly of great visual value, though there is no conclusive proof that the purple stain itself has actually any direct influence on sensation. Although complete rest—that is, darkness—causes an accumulation of this secretion the function proceeds during exposure to light.

The next fact of importance in this consideration is the contraction of the cone-myoid, which may be either due to a direct action of light on protoplasm, comparable to what has been observed in *peiomyxa palustris*, or to a change produced indirectly, the cone-myoid contracting in consequence of some stimulus, possibly chemical, received from the pigment cell.

Prolonged exposure to an intense illumination—direct sunlight, for example—causes actual changes of so pronounced a character that the outer segments of the visual cells are altered anatomically as well as functionally, and this alteration may persist for many months or even remain permanent.

The fundamental idea of vision seems to be to connect visual impression with muscular action, so that the animal may move out of danger, protect itself, or find its food. There is no necessary consciousness associated with any such visual influence, even in the case of animal forms where different wave lengths produce a difference in the muscular movements induced. In the case of the *daphnia*, for example, the experiments of Lubbock demonstrated that this tiny crustacean, with its feebly developed nervous system, is capable of distinguishing between light of different wave lengths, and that it is influenced particularly by the rays that correspond to what we know as yellow-green. It is unnecessary, and surely unreasonable, however, to conclude that the daphnia has any real conscious vision as we understand it in ourselves—still less a true colour sense. As an instance of how eyes may be developed, and prove serviceable for the production of a muscular action beneficial to the individual, no better could be brought forward than that observed by Semper in the *onchidium*. This land-snail lives close to the sea-shore, and the same shore area on certain coasts is frequented by the periophthalmus, a fish which leaves the water in search of food. Wherever this particular foe exists, and nowhere else, the local onchidium exhibits numerous highly developed eyes on its back, each having retinal cells, pigment, and optic nerve. In these dorsal-eyed onchidia, and in these alone, the skin of the back is thickly set with minute glands containing concretionary pellets, which are discharged by a general contraction of the body in hundreds. Such a contraction is induced, according to Semper, when the dorsal eyes give notice of the approach of this enemy.

Protective changes in colour under the influence of their surroundings occur in many animals, particularly in many fish and amphibians. The pigment is contained in contractile cells in the skin, and Lister has shown that the activity of these cells affecting the distribution of pigment is dependent on vision. Pouchet subsequently proved that the reflex takes place through the sympathetic nerves, the intensity of the nerve-current excited and the completeness of the contraction of the pigment-bearing cells being proportional to the brightness of the light reflected from surrounding objects. It is not a question of the animal consciously assuming a protective shade, but an instance of a visual impulse provoking a muscular contraction.

As we ascend in the animal scale we get further centralisation of the nerve mass, and find the visual apparatus intimately connected with it. Even in the case of the vertebrate brain it has been asserted that in all probability each part was primarily independent, and the division connected with the optic nerve was one of conspicuous importance. In the lower vertebrates—fishes, amphibians, reptiles, and birds—we still find the central connexion of the optic nerves almost confined to one part, the large optic lobes corresponding to the corpora quadrigemina of mammals. But as we ascend the scale this part of the brain becomes progressively smaller and less developed and seems to be mainly instrumental in the transmission of visual impulses that are to be immediately—that is, without reference to the visual cortex—conveyed as reflexes by way of motor nuclei to muscles, such as those for movements of the iris, and possibly to some extent of the eyeball—movements that can occur independently of sensory vision. There is absolutely no evidence that there is any difference in the character of the original impulse, or in the optic nerve-fibres that convey it, to distinguish what will be a mere muscular reflex and what will be a conscious impression. As to the manner in which such fibres are connected with visual cells, so that there may be, as it were, double central representation (sensory and reflex) of every part of the retinal area, we are still ignorant. It is possible that this is brought about by lateral communications between the processes of retinal ganglion cells of one or other layer, but more probably it is effected by a collateral from the axon of the last retinal neurone.

The visual fibres, strictly so-called, take, at least mainly, another course in the higher vertebrates. In man, for example, they pass from the optic tract to the external geniculate body and pulvinar, and thence the impulse is conveyed by fibres which traverse the posterior end of the internal capsule and pass, as the optic radiations of Gratiolet, to the cortex of the calcarine fissure and its immediate neighbourhood. The crossing of the optic nerve fibres at the chiasma so as to produce unilateral representation of the corresponding half of each retinal field; the bilateral representation of each macula; the association fibres which bring the cortical region of visual projection into relation with the much more extensive area of visual representation; the question of a distinct unilateral representation of each ocular visual field; and the arguments for and against a separate cortical area instrumental in colour perception must be left with a bare mention.

As regards the receiving apparatus, the visual fibres end by communicating directly, or indirectly through a nervous felt-work, with cells of the visual area, and destruction of this part of the cortex causes immediate blindness of a corresponding part of the field of vision. It would appear that the upper and lower lips of the calcarine fissure of one occipital lobe correspond respectively to the upper and lower parts of the homonymous halves of both retinæ, and that the fovea is represented along the entire length of the fundus of the fissure.

But whether the cells of the calcarine cortex are the seat of conscious impressions or merely constitute a stage in the path to yet higher centres, and whether the same cerebral cell is capable of appreciation of differences in colour as well as of difference in amount of light effect, must remain debateable questions. So much only may be observed, that this part of the cortex is particularly rich in cells, mostly of small size, while there is no reason to regard a small nerve cell as inferior to a large one in functional activity.

IV.—With regard to the broad facts of our recognition of the conducted impulse we have evidently two distinct sensations dependent upon light—colour and brightness; both influenced by differences in wave rapidities or wave-lengths.

On gradually reducing the intensity of the spectrum the colours fade and cease to be recognisable, but not simultaneously. Of these two sensations, light and colour, that for light is the one that persists with the smallest recognisable stimulus and is presumably the more elementary. The most elementary visual sensation is that derived from waves near E, that is for green. Clinically we have additional proof of this difference, for example, in cases of optic nerve disease with failure of conduction, colour sensation disappearing before that of light. Moreover, in the case of total congenital colour-blindness the brightest part of the spectrum is also in the green, about the line E, just as we find it to be on sufficiently diminishing the intensity of the solar spectrum to the normal eye. In fact, the appreciation and conduction of the stimuli associated with colour sensation seem to be more delicate than for light; a greater stimulus is needed to excite it, and it is more readily affected by any failure in the conducting path. The longest visible waves are recognisable as a colour (red) at the same time as they become visible as light, while in the case of shorter waves near E (green) there is a marked interval

between the intensity necessary for the perception of light and that for colour. Green, indeed, affords us the best clinical test of early failure of conduction, the appreciation of the colour failing, while that for light persists.

Of these two sensations there is reason to regard light perception as the more *primitive*, and the primitive type of visual cell is pigmented epithelium. We are encouraged, then, to consider this part of our retina as mainly concerned in the appreciation of light as distinguished from colour, and many facts support this view. Thus, in disease of the pigment epithelium there is difficulty in appreciating differences in the amount of light. Again, when changes have occurred in the pigment cells, when the eye is kept in the dark for about an hour, there is a remarkable increase in the sensitiveness of the retina to light. We may infer that the chemical action, induced by light on a particular secretion of the pigmented epithelium, is intimately associated with the causation of the effect recognised as *light-sense;* and the next step is to inquire how the impression is conveyed from the pigment cell, whether by rod- and cone-cells indifferently, or mainly by one of them. Although the power of appreciating a faint light stimulus is so markedly increased as a whole by "dark-adaptation," we find that this does not apply to the entire visual field, and does not apply equally to all parts of the field where it is increased. Thus in the central area the light-sense is actually diminished under these conditions; and whereas it is increased outside the central area, it is relatively more augmented as we approach the periphery. That is to say, it is not increased at all where cones alone are present, and the increase becomes more marked as the rods become more and more the predominant element. It has therefore been argued, with reason, that the rods are the elements concerned in the appreciation of light, or, rather, of the change produced in the pigment cells by light, while the eye is thus adapted; although whether or not the retinal purple is visually concerned may be considered still an open question. So definite is the physiological area of diminished light-sense in this condition that it can be shown to correspond with the projection of the rod-free foveal retina.

The only possible argument that can be adduced against this conclusion is the possibility that there may be a difference in the behaviour of the pigment cells themselves, in the central and peripheral regions of the fundus, but no evidence in favour of this has ever been brought forward. Granted, then, that the rods have this particular function, it by no means follows that the cones are not serviceable in the appreciation of light in ordinary illumination, though their peculiar office is presumably concerned with the recognition of differences of stimulation associated with variations in wave-length recognised as colours. Indeed, we know that light is ordinarily appreciated with marked efficiency by the macular area, but it is possibly always in virtue of the same function that is concerned in colour vision, white light being recognised, not as a simple result of stimulation, but as a consequence of, say, three simultaneous stimuli any one of which alone would excite a central impression of colour. It would seem as if a minor amount of stimulation that can be appreciated only by the rods must be excited before the cones come into functional activity. It is possible that the first action of light on the pigment cell is instrumental in providing a product of secretion or decomposition that is required so that the finer differences in wave-lengths be appreciated by the cones and the colour-sense stimuli be thereby initiated. Very possibly the movement of the cone-myoid is of service in this association.

PURE BUTTER.—Recently a firm of grocers at Rhyl sued a Liverpool firm of butter merchants for costs sustained in defending an action in which they were charged with selling butter adulterated with boric acid. Judge Lloyd decided in favour of the plaintiffs on the ground that butter containing boric acid was not absolutely pure. The case was then taken to the High Court and remitted back to Judge Lloyd for consideration as to whether it was pure butter according to the trade. At the Rhyl County Court on June 22nd it was stated that the plaintiffs had consented to a judgment for defendants and agreed to pay £15 costs. His Honour consented to the settlement, but remarked that although butter which contained boric acid as a preservative might be regarded as pure in the trade, it could not be absolutely pure according to the customers' idea.

UNUSUAL COMPLICATION FOLLOWING GASTRO-JEJUNOSTOMY.[1]

BY W. H. BROWN, F.R.C.S. IREL.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

I RELATE the following case to offer another instance of a good result following operative interference when there seemed to be but a forlorn hope of giving relief.

The patient, a woman, aged 62 years, had suffered for many months from pain after food, the pain gradually becoming most acute so that opium in full doses was needed to obtain anything like comfort. Latterly regular attacks of vomiting occurred about every 48 hours, when most of the nourishment taken during the preceding two days returned. No tumour could be felt but the symptoms all pointed towards pyloric stenosis. As the condition of the patient was getting unendurable I decided, after consultation with Dr. T. Churton, to open the abdomen to see if anything could be done. At the operation I found the pylorus greatly thickened and masses of enlarged glands constituting too great an area of disease to be attacked with any degree of safety. I therefore joined up a loop of jejunum to the stomach, using Senn's plates as the scaffold of anastomosis.

For the next two weeks all went as well as such cases usually do; the vomiting ceased and the pain gradually subsided. At the end of that time, however, the symptoms of obstruction began to reassert themselves, the pain again grew severe, and again the regular vomiting began, the amount corresponding with the quantity of fluids taken. It seemed clear that the new opening had for some reason or other ceased to be effectual. I therefore was face to face with a most discouraging chain of events and the patient herself was as badly off as she was before she submitted herself to operative interference. I decided to act on the assumption that the new opening between the stomach and the jejunum had closed and determined to re-open for the purpose of ascertaining the reason. Accordingly I re-opened the abdomen and I found that the junction between the bowel and the stomach externally was quite satisfactory. I then made an incision into the stomach two inches above the junction, and putting my finger inside found that all trace of the bone-plate had disappeared and also that all trace of the opening was absent. After a minute or two I felt the edge of the oval cut of the former operation and pressing firmly in the centre of this tore through a membrane by which the opening had been occluded. My finger then passed easily into the bowel and I stretched the opening freely in all directions. I then closed the exploratory incision into the stomach and finished the operation in the usual manner. After a day or two, during which time vomiting was incessant, improvement set in. The pain again left and it has not since returned. The patient is able to take light food and the vomiting has ceased. She is now out of bed daily and is gaining strength.

I have had occasion to operate for the relief of pyloric stenosis a good many times and in each instance I have used Senn's plates, but never before has the disaster I have related taken place. The membrane through which I tore was about as thick as ordinary note-paper. I do not know what occasioned the formation.

I said at the commencement of the notes of this case that I related it to add to the number of recorded surgical successes under desperate circumstances. With the condition which I have related to hold one's hand was to let the patient die in great distress; to operate again gave her one chance, but it also exposed her to the risk of death upon the operating table. Problems such as these come before us only too frequently and end only too often disastrously. I think it right, therefore, to put upon record this case, as it may possibly afford a guide as to the line of action to be decided upon should failure to relieve attend upon operation for a like condition.

June 24th.—The patient is now well, taking ordinary food and doing her ordinary work.

Leeds.

A CASE OF PRIMARY CARCINOMA OF THE VERMIFORM APPENDIX.

WITH REMARKS.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN AND LECTURER ON PATHOLOGY AT ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN.

A WOMAN, aged 26 years, was admitted into St. George's Hospital, on March 26th, 1900, under the care of Dr. F. G. Penrose, with a fourth attack of appendicitis, the first attack having occurred in January, 1899. On March 27th, 1900, the day after admission, the appendix was removed by Mr. A. Marmaduke Sheild. There was a small peritoneal adhesion connecting the apex of the appendix with the posterior surface of the uterus. No enlarged glands or anything in any way suggesting secondary growths were seen at the time of the operation. When the appendix was cut open a globular mass, a little larger than a marble, was found near the apex arising in the mucous membrane. It was somewhat caseous in appearance and suggested the possibility of tuberculous disease. The patient recovered from the operation, but during the middle of April she had an erratic temperature with some pain on the left side of the abdomen. This, however, subsided and she went to the convalescent home in May. I have recently (June 27th) heard from Mr. Sheild that the patient is losing flesh and strength, and that it is possible secondary growths are developing in the abdomen. The appendix was sent to me, for microscopical examination and report, by Mr. Sheild, to whom I am greatly indebted for permission to publish this interesting case.

Microscopical examination of the vermiform appendix showed, most unexpectedly, that it was the site of primary spheroidal-celled carcinoma. In its earliest stage the growth was seen to be limited to the mucous membrane (*vide* Fig. 1), but its histological structure in this situation was exactly the same as in other sections of adjacent parts of the appendix, where it was seen to be widely infiltrating the muscular coats and extending nearly up to the peritoneal covering (*vide* Fig. 2).

FIG. 1.

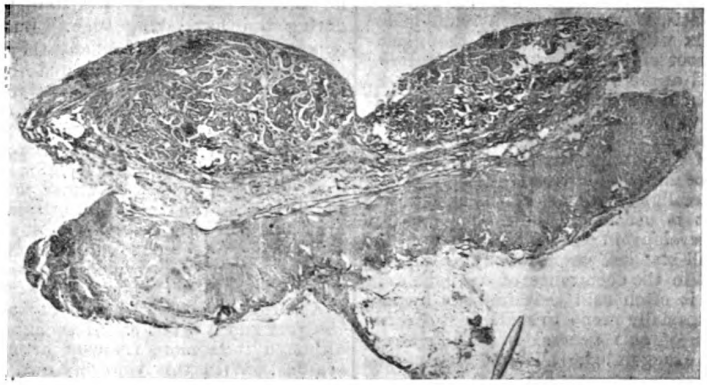

Photo-micrograph No. 1. Section of vermiform appendix showing carcinoma beginning in mucous coat. × 6.

FIG. 2.

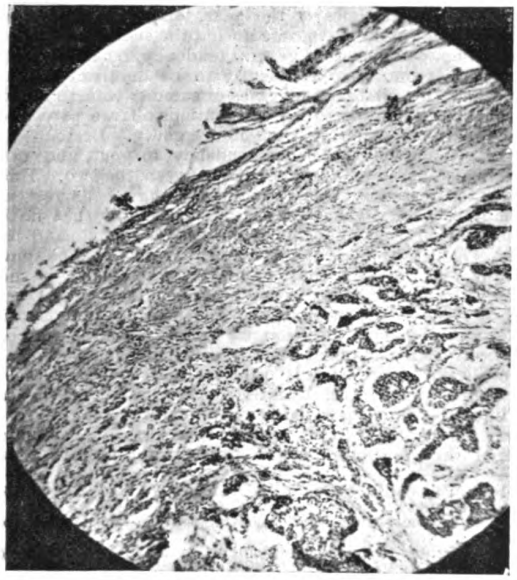

Photo-micrograph No. 2. Section of vermiform appendix showing carcinoma invading muscular coats. × 126.

The facts that (1) the growth was most extensive in the mucous coat, (2) that it could be traced outwards into the muscular coats, and (3) that there was no growth on the outside of the peritoneum, showed that the growth originated in the mucous membrane of the appendix, and that it was not a secondary growth either implanted on the peritoneum or arising as a result of embolism within its substance. I have several times seen secondary growths, in generalised malignant disease of the peritoneum, invading the appendix from without. If such an appendix were removed during life it might, if only superficially inspected, give rise to an erroneous diagnosis of primary malignant disease of the vermiform appendix. In the case of secondary malignant disease of the bowel due to emboli of infective tumour-cells the growth arises, and is most prominent, in the sub-mucous or muscular coats and only secondarily involves the mucous membrane. For the excellent photo-micrographs I am greatly indebted to the kindness of Mr. E. J. Spitta of Clapham, and Mr. Harold R. D. Spitta, a senior student of St. George's Hospital.

THE RARITY OF THE DISEASE.

Primary malignant disease of the vermiform appendix is not mentioned in Hawkins's work on "Diseases of the Vermiform Appendix" (1895) or in Allbutt's "System of Medicine." Kelynack in his monograph on "The Pathology of the Vermiform Appendix" (1893) could not bring forward any undoubted case, but he refers to three cases in a tabular statement drawn up by Leichtenstern, and to a case of colloid carcinoma described by Draper, which he (Kelynack) thinks probably arose in the ileo-cæcal valve.

Lafforgue [1] collected no less than nine cases of primary carcinoma of the appendix. Mosso and Daunic [2] found the

[1] Thèse de Lyon, 1893.
[2] Bulletin de la Société Anatomique de Paris, Novembre, 1897.

appendix of a woman, aged 50 years—who had not presented any special symptoms pointing to disease of the vermiform appendix, death being due to morbus cordis—to be affected with carcinoma. The appendix was four centimetres in length and 45 millimetres in its greatest circumference. On section the muscular coats could be distinguished surrounding a tumour growing in the inner coats. In this way it resembled the section of the early stage of carcinoma seen in my case (Fig. 1). The growth was regarded as a columnar-celled carcinoma with a transition to the spheroidal-celled type. Letulle and Weinberg [3] in a careful investigation into the histology of 12 cases of obliterative appendicitis discovered quite unexpectedly that two of their cases showed microscopical evidence of developing carcinoma at the level of the cicatricial obliteration of the tube. Wright [4] described a columnar-celled carcinoma of the appendix close to its insertion into the cæcum which had perforated near this spot and set up fatal peritonitis. It must be admitted that this last case and one recorded by Thiersch [5] are very much the same as carcinoma of the cæcum—a much commoner condition. In a boy, apparently the subject of appendicitis, Warren [6] found a round-celled sarcoma of the appendix with involvement of the glands extending back to the root of the mesentery. H. Gilford [7] removed the cæcum and appendix from a woman, aged 27 years, who had had trouble in that region for 13 years. It is described as a sarcoma around a calculus in the vermiform appendix, but after reading the case I do not see any convincing reason for doubting that the microscopical appearances were those of granulation tissue.

The rarity of primary malignant disease of the appendix is rather striking when it is considered how comparatively frequently carcinoma develops in another annexe of the alimentary canal, the gall-bladder, which resembles it in its liability to infection and in the occurrence of a calculous or lithogenic catarrh.[8] It is often said that fœtal relics and atrophying organs are especially prone to malignant disease, but whatever the value of this general statement, and I believe it to be rather exaggerated, it is not true of the vermiform appendix.

Primary malignant disease of the appendix is perhaps not so rare as would appear from literature for two reasons. 1. Because in the early stage of carcinoma the appendix may be removed for symptoms of appendicitis, and in the absence of a routine histological examination of removed appendices some cases may thus escape recognition. The present case is an instance in point, the condition naturally being unsuspected until a microscopical examination was made. It is the only case I have met with in a histological examination of 34 morbid appendices. 2. Because if the disease runs its course without interference a large mass of growth would probably result which might become adherent to the cæcum, the bladder, or the bowel, and then be thought to have originated there, rather than in such an unusual site as the appendix.

CLINICAL FEATURES.

It is remarkable that in three of the cases referred to above there were practically no clinical symptoms. When symptoms are present they are those of appendicitis. It is possible, on the analogy of tumour myelitis in the spinal cord that the growth sets up appendicitis, or, as suggested by Wright's case, that a small perforation may set up peritonitis around it. On the other hand Letulle and Weinberg's discovery of carcinoma developing in cases of obliterative appendicitis suggests that the growth is related to appendicitis much in the same way that carcinoma of the gall-bladder is related to cholelithiasis, which is of course the outcome of cholecystitis. It is, however, quite possible that the growth alone, without the addition of any ordinary inflammation, may account for the symptoms in some instances.

It may be worth while putting forward the suggestion that when apparently multiple primary (nodular) malignant disease of the liver occurs the vermiform appendix should always be carefully examined at the necropsy. It is hardly likely that multiple secondary growths would develop in the liver while the primary growth in the appendix is so small as to require microscopical examination. But it is quite conceivable that in a case of multiple carcinoma, apparently primary in the liver, the really primary growth might have been in an appendix previously removed for supposed appendicitis.

ON THE TREATMENT OF THE SO-CALLED "HAY-FEVER" OR SUMMER CATARRH.

BY KARL GRUBE, M.D.

SUMMER catarrh (*catarrhus æstivus*), also called "hay-fever," was first described at the beginning of this century by Dr. John Bostock [1] of London, who himself suffered from it. As the name implies, the affection occurs during the summer months, but chiefly at the time when grass flowers and during the haymaking time. But while many patients only suffer from it when they come near a hay-field others are also affected by any strong-scented flowers or by ordinary dust; several of my patients were always attacked on railway journeys in hot and dusty weather. The catarrh affects the mucous membranes of the eyes, nose, and lungs. In the same person the mucous membrane of all the parts mentioned may be affected or the catarrh may be limited to either the eyes and nose or to the bronchi. In the intervals between attacks the patients are either perfectly well without any affection of the respiratory organs, or there may be a tendency to catarrh of these organs or a chronic morbid condition of the nasal mucous membrane with thickening.

According to Beard,[2] hay-fever may arise at any season of the year and it is not at all peculiar to summer or autumn, although it is more frequent or more persistent at these seasons. With this view my own experience agrees, as I have seen cases of so-called hay-fever as early as February.

In most of my cases, and in all cases which were treated successfully, a gouty tendency could be traced to be underlying the local affection, the patients either coming of a gouty stock without themselves having any other symptoms of gout or suffering from gout in some form or other—e.g., gouty rheumatism.

Strictly speaking the universally used term "hay-fever" is misleading, for, as I have already mentioned, the catarrh is not produced only by grass or hay, nor is it entirely limited to the summer months. One frequently finds on inquiry that persons who pronounce themselves to be suffering from hay-fever also suffer more or less freely from catarrhs at other times of the year, only the attacks are more frequent and more severe during the summer. In these cases, then, one sees that general tendency to catarrh of the mucous membranes so frequently to be observed in gouty subjects. Of course, not all cases of summer catarrh are due to gout, but according to my observations a large percentage of the patients suffering from it are gouty. Bostock himself mentions that he had a tendency to gout, and other writers also speak of a connexion between the two. I may quote, for instance, Gueneau de Mussy,[3] Leflaive,[4] and Lermoyez.[5] Sir Dyce Duckworth [6] also states that he has sometimes noticed the connexion between gout and hay-fever. A further proof of this connexion may also be found, I think, in the fact that hay-fever, like gout, is more common in England than in any other country.

If it should be true that the gouty disposition is often underlying the local affection we can *a priori* only expect success from a treatment that is directed against both. I have always acted on this principle and have always laid great stress on a careful and strict regulation of the diet on lines that are so well known as not to require to be detailed here. The local treatment consists in the application of the Neuenahr waters in the form of inhalations,

gargle, and nose-douche. In cases in which there have been muscular and articular pains in addition to the catarrhal affection hot baths and massage have proved to be of great use. The best time for this sort of treatment, according to my experience, is during the months of May and June—that is to say, before the attacks of hay-fever have begun to show themselves. July I should not recommend; in August and September, however, I have treated cases with success. There are cases of hay-fever which do not respond to the treatment. These I have always found to be cases in which there was no history of gout, while in those cases in which the combination of gout and summer catarrh existed I have scarcely ever failed to obtain a good result. The following is the history of a few of my cases.

CASE 1.—The patient, a female, aged 19 years, had suffered from hay-fever for many years. There was a history of gout. The affection generally began towards the end of May. Hay, roses and other flowers, as well as heat and dust, immediately brought on an attack which began with sneezing and running at the eyes and nose, and which after a short time was followed by coughing. During June and July the attacks were of almost daily occurrence. In other respects the patient was perfectly well. There was some thickening of the mucous membrane of the nose, especially on the left side. Bleeding from the nose was easily brought on. The treatment as described above was carried out in April and May, 1897, with the result that there were no attacks of hay-fever during that summer. A second shorter course of treatment was thought advisable in April, 1898. There has been no recurrence of the attacks of hay-fever up to the present time (March, 1900).

CASE 2.—The patient, a female, aged 36 years, had suffered from hay-fever since the age of 15 years. Both her parents were gouty. The patient herself had suffered from rheumatic pains and articular swellings. She had severe attacks of hay-fever from May till August, recurring almost daily and much exhausting her. During the attacks there was great swelling of the upper part of the face, intense frontal headache, much secretion from the eyes and nose, together with coughing and a wheezing respiration. Local treatment of every description had been useless. Relief was only to be obtained by residing in a bracing place at the seaside. The patient was treated at Neuenahr during part of May and June, 1897, and though the attacks became less violent they did not entirely cease. The treatment was repeated in the following year with the result that no attacks of hay-fever occurred during that summer, nor has there been any recurrence since 1898, but I should mention that the patient has lately been more subject to rheumatic pains.

CASE 3.—In this case a history of gout was obtainable. The patient, a female, aged 42 years, was first treated for hay-fever at Neuenahr during 1895 with good results. She remained free from attacks during the following two years. In 1898 a relapse occurred which made her return to Neuenahr; she had after that no more attacks during 1898 and 1899.

CASE 4.—The patient, a girl, aged 10 years, came of a very gouty family and was herself a very delicate child. She has been suffering from severe attacks of hay-fever for the last four years. She was quite disfigured by the attacks. Her face was swollen and red, her eyes were inflamed, and there was constant running at the nose together with coughing and wheezing respiration. She contracted the attacks everywhere and from all sorts of causes, but especially from heat and dust. When she arrived at Neuenahr she was in the midst of one of her most severe attacks and was very prostrated. During the following four weeks she kept quite free from the attacks, nor did the long journey to St. Moritz affect her, although the weather was hot and dusty. She has since kept wonderfully well.

CASE 5.—This case is one of those treated without any success. The patient had suffered from hay-fever and asthma for several years. There was no history of gout. The attacks occurred almost daily during May and June. They began in the usual way with sneezing and increased nasal secretion, but their chief feature was violent coughing, a feeling of severe tightness round the chest, and a difficulty in breathing. The usual treatment was carried out but had to be given up after its ineffectiveness had been proved.

The following are the conclusions to which I am led. 1. There are cases of summer catarrh (so-called hay-fever) which can be cured, or at least relieved, by treatment with the waters of Neuenahr. 2. The cases especially suited for this treatment are those in which the affection is a part of the gouty dyscrasia. 3. Cases without a history of gout do not seem to be benefited by the treatment.

Neuenahr, Germany.

EXERCISES IN THE TREATMENT OF LATERAL CURVATURE OF THE SPINE.

BY NOBLE SMITH, F.R.C.S. EDIN., L.R.C.P. LOND.,
SENIOR SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL, LONDON.

THE beneficial influence of gymnastic exercises upon the general health of the body has been recognised for ages and it is needless, in discussing the present subject, to dwell upon this fact further than to state that in treating curvatures of the spine everything which benefits the general health will materially assist other treatment.

My present purpose is to consider the local effects which may be produced upon a crooked spine by specified muscular exercises, either by correcting the shape of and strengthening the joints, or by strengthening any particular set of muscles connected with the deformity. In the first place it should be noted that it is impossible to lay down any hard-and-fast rules for gymnastic exercises by which to deal with every instance of curvature, because cases differ to such an extent that what is suitable to one individual would be totally wrong for another. Moreover, patients differ as regards the muscles they bring into use in carrying out the same movements. I will in the first place describe briefly the various kinds of lateral curvature and the application of gymnastics to their peculiar requirements.

CLASS 1.—That in which the most notable condition is debility occurring after illness or from some other cause. In these cases the muscular system being especially affected the patient is unable to hold his spine erect except for short periods, but in the early stage there is not any well-marked bony deformity. For such a condition a course of general active and passive exercises of the trunk and neck, and also of the legs and arms, will have a beneficial effect. As a rule, these exercises should be carried out while the patient is in a recumbent position. The general health of these patients always requires treatment by means of a nutritious diet and tonic medicines, some form of lime being especially beneficial. Massage is also helpful. It is usually also advisable to limit the amount of voluntary active movements in order to avoid producing fatigue.

CLASS 2.—In this class we find, in addition to the above symptoms, laxity of the ligaments of the spinal joints. For these patients exercises will be beneficial, but greater care must be taken to prevent the spine from subsiding into curves during the intervals between the exercises.

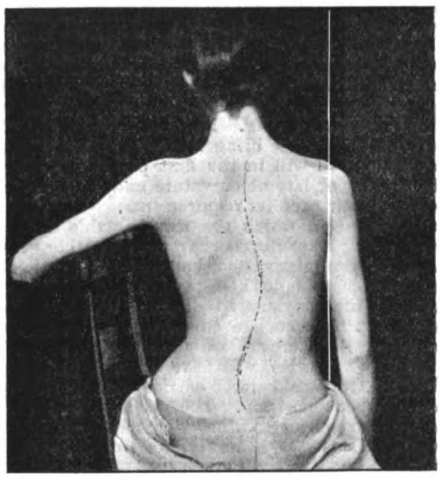
CLASS 3.—In which alterations in the form of the bones has already occurred. In these cases the exercises must be directed not only generally, but specially, in order to overcome these curves. For instance, the special exercise to be presently described to correct rotation is one of the most important.

CLASS 4.—In which the curves are more severe. For these patients some good may be done doubtless by a course of exercises, but less permanent effect must be hoped for than in the less severe cases.

In Class 1 mentioned above it is nearly always desirable to commence treatment by exercises and in many cases with the addition of massage. In Class 2, also, exercises may be carried out, but the patient should be carefully watched to determine whether he is really recovering and to detect when the disappearance of curves is more apparent than real. In Class 3 and Class 4 a combination of methods must be brought to bear upon the case.

Description of exercises.—A great variety of complicated exercising machines have been devised and used from an early date in the study of this deformity, but although these apparatus are very beneficial under some circumstances, it should be the object of the surgeon to simplify as far as possible the various movements carried out, with the view of teaching the patient to continue the treatment by himself as far as possible subsequently.

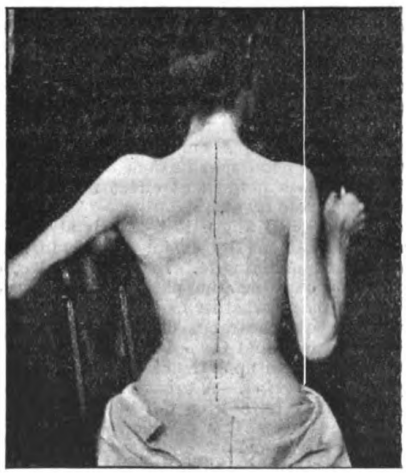
In the early periods of treatment of any case, however, the knowledge of the surgeon and the efforts of the skilled teacher are both necessary, and unless the curvature be very



slight the medical supervision is required for a considerable time.

General exercises.—I have already stated that, as a rule, the patient should rest in the recumbent position whilst carrying out the general exercises. The object of the recumbency is to remove the weight of the body from influencing the curves.

We almost invariably find that where there is general debility and a weak muscular system there also exists laxity of the joints. Under such circumstances whenever the spine is in an upright position, whether the patient be standing or sitting, there is a certain deforming influence upon these lax joints caused by the superincumbent weight, and the spine consequently tends to give way in one or other direction.

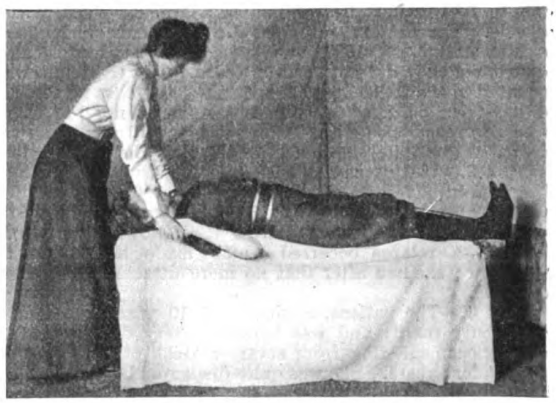


The object of general exercises is to strengthen the muscles and also, by bringing more blood to the weak parts, to nourish and strengthen the whole spine. The test as to when a patient may safely undertake exercises in an upright or sitting position must be his ability to control his spine in a straight posture for a sufficient length of time. For instance, when we have first examined the case the patient, upon sitting in a chair, will, after a certain short period, have relapsed as regards his spine into one or other or several curves. When the time has arrived that he can sit up easily with the spine in a perfectly normal position not only as regards lateral but also in respect to antero-posterior posture for at least five minutes, then we need not restrict the exercises to the recumbent position.

FIG. 1.

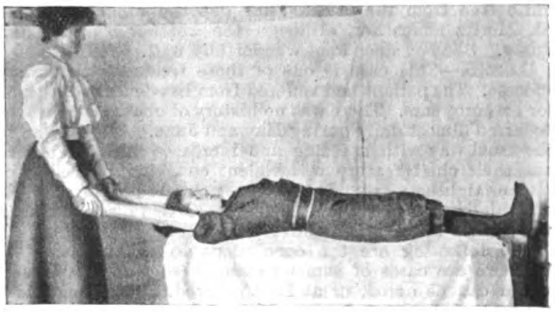
Dorso-lumbar curvature, the dorsal curve being most prominent about the tenth dorsal vertebra.

FIG. 2.



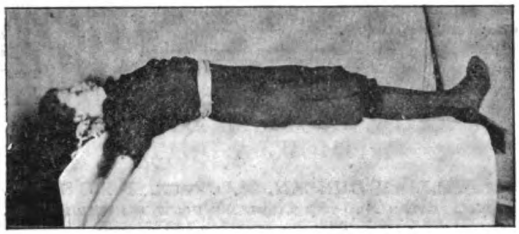
The same patient as in Fig. 1 drawing back the elastic expander with the right arm, thus using the muscles between the shoulder and the spinous processes of the deflected dorsal vertebræ, straightening the whole spine and un-rotating the vertebræ. The vertical lines from the outer side of the pelvis show the relative positions of the side of the body, without and with the active exercise.

FIG. 3.



The exercise for drawing back the prominent side of the thorax. Here the dorsal curve was to the left. The patient in Fig. 1 and Fig. 2 would have done this exercise with the left arm.

FIG. 4.



Arm extension, first position, with resistance by the patient. In the second position the arms are raised and the operator resists.

FIG. 5.

Arm extension, second position, in which the operator resists.

FIG. 6.

Arm extension without resistance, second position. In the first position the arms are flexed and the fingers touch the shoulders.

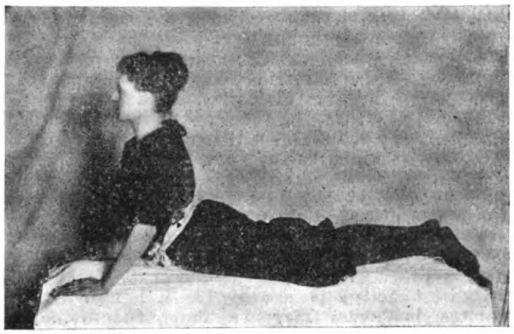
FIG. 7.

Arm extension, third position.

FIG. 8.

Simultaneous leg elevation. The arms are extended to balance the body. This exercise has a powerful effect upon the abdominal and lumbar muscles and has to be attained by gradual slighter movements.

FIG. 9.

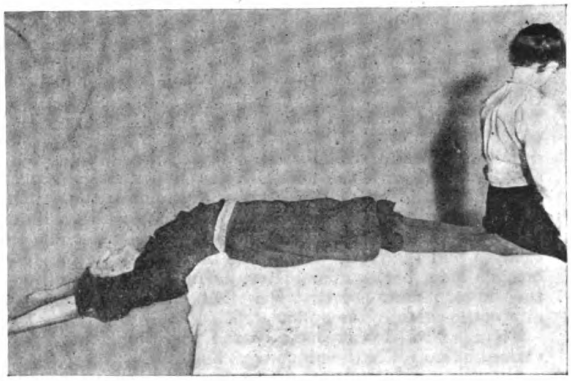


Simultaneous leg and arm circling. The combination of these exercises is only carried out in exceptional cases and requires considerable strength.

FIG. 10.

This figure shows the first position for the exercises in Fig. 11 and Fig. 12.

FIG. 11.



Body flexion backwards and forwards. his exercise requires considerable practice before it can be done *evenly* to the extent shown.

FIG. 12.

Kneeling body movement. It would require many figures to show the details of this exercise. Before it can be carried out satisfactorily more simple degrees of the position have to be practised.

FIG. 12.

Backward bending with legs fixed. If forward bending to a sitting position is required the patient must have the knees bent over the edge of a shorter couch and there fixed.

Exercises to act directly upon the curves.—In order thoroughly to realise the effect of exercises upon a curved spine it is necessary to consider carefully the exact action of the muscles which we propose to bring to our aid and the exact position of the parts which are distorted.

One exercise which has been recommended for acting directly upon the dorsal curve has been devised with the object of drawing out the concave side of the curve by use of the arm of that side, but this exercise tends to increase the twisting of the spine which is the most serious part of the deformity.

The muscles which extend from the arm to the spine are the trapezius, the rhomboidei, and the latissimus dorsi and these are attached to the spinous processes of the vertebræ.

It should be remembered that the spinous processes are directed, in consequence of the rotation of the vertebræ, towards the side of the *concavity* and that the rotation is the part that offers the more serious obstruction to treatment. The effect of this exercise is obviously to draw the spinal processes further in the direction of the concavity and consequently to increase the rotation.

The plan of special exercises which I have devised for acting upon the dorsal rotation consists in the use (1) upon the *convex* side of the curve of the muscles above referred to, with the object of drawing the vertebræ round towards their proper position; and (2) upon the *concave* side of the curve of the muscles which extend from the arm to the front of the body, with the object of drawing backwards that prominent side of the thorax. Although this plan of exercise acts directly only upon the dorsal curve, yet the resistance of the pelvis to the action of the arms tends to twist the lumbar part of the spine in the opposite direction and thus produces the exact action that is required. If more direct action is needed for a lumbar curve the quadratus lumborum may be brought into use upon the *convex* side of this curve, and this is best done with the patient in the recumbent position. The object of this system is to lessen the curves upon their convexities and to rotate the vertebræ back to their normal position.

Slight variations in these exercises must be made to suit individual cases, as there is nearly always some difference in the form and condition of the curves. The general exercises of the erector spinæ muscles of both sides should, as a rule, be carried out in addition to the special exercises now described and avoidance of fatigue and suitable rest should be observed.

In the earlier stages of treatment the special exercises should be conducted while the patient is lying recumbent both in the supine and prone position, but it will perhaps suffice here to describe these exercises as carried out in the sitting position.

For this exercise upon the convexity a hook should, in the first instance, be placed, as a rule, on a level with the top of the patient's shoulder while sitting, but often it is necessary to vary this position higher or lower before the desired effect upon the curve can be attained. It is remarkable how plainly this action when correctly performed, affects the curve. In slight cases the spinous processes may be drawn completely into a straight line at once and the projection of the ribs depressed towards a plane with the opposite side, showing that the vertebræ are rotated into or towards their normal position. Of course, this effect only lasts as long as the muscles are held in contraction, but the value of the exercise is thus proved, and the practical result is eventually a permanent lessening or removal of the rotation (Fig. 1 and Fig. 2).

In the exercise upon the front of the thorax (Fig. 3) the effect is less evident. The patient, in a sitting posture, draws the elastic cord forwards from a fixed point on or about a level with the shoulder on the side of the dorsal concavity, this point being situated behind the patient. This plan brings into use the muscles between the arm and the front of the thorax (the pectoral muscles), which thus tend to pull the front wall of the thorax, unduly prominent on this side, backwards. Here, as in the former instance, the surgeon must see that the effect is beneficial before he allows the exercise to be practised.

Figures 4 to 13 show some of the postures adopted in the various exercises in the recumbent position.

It would be almost impossible to give illustrations of all the exercises which may be used beneficially in the treatment of curvatures of the spine; they have to be varied to meet the requirements of each individual case. Those given above will, however, afford a fair illustration of some of the more important positions produced in this treatment.

Queen Anne-street, W.

100 CONSECUTIVE CASES OF ABDOMINAL SECTION IN HOSPITAL PRACTICE WITHOUT A DEATH.

BY WILLIAM DUNCAN, M.D. BRUX., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL; SENIOR PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

SUCH a series of cases as that about to be given is sufficiently rare to merit publication; indeed, I am not aware that a similar series has occurred hitherto in this country—at all events it has not been recorded.

On Oct. 7th, 1897, a patient on whom I had operated for ruptured extra-uterine gestation at the Chelsea Hospital for Women died suddenly on the seventh day from pulmonary embolism when she seemed to be doing perfectly well. From that date up to now (June 10th, 1900) all my sections at the above hospital are included in the following table. The cases, I may add, were the only ones admitted into my wards which required abdominal section. There was no choosing of favourable cases—indeed, the ninety-eighth case was about the worst of the series, being a suppurating ovarian cyst with pedicle tightly twisted three times, and the cyst wall was universally adherent, anteriorly to the parietal peritoneum and in the rest of its extent to the intestines, so intimately that the latter could only be freed by leaving a thin layer of the cyst wall adherent to them.

100 Abdominal Sections performed at the Chelsea Hospital for Women between Oct. 7th, 1897, and June 10th, 1900.

Uterine fibroids:		Suppurating broad ligament cyst	1
hysterectomy	17 \} 20	Tubo-ovarian cysts (two simple and five suppurating)	7
myomectomy	3 \}	Diseased and adherent appendages:	
Ovarian cysts:		right appendage removed	4 \} 12
left	6 \} 23	left appendage removed...	2
right	9	both appendages removed...	4
double	4	adhesions broken down	2
dermoids (one single and three double) ...	4	Ventral hernia	1
Ventro-fixation	7	Exploratory incisions ...	3
Extra-uterine gestation:			100
ruptured	6 \} 11		
unruptured	5		
Pyosalpinx (double)	9		
Hydrosalpinx (one single and three double) ...	4		
Parovarian cysts...	2		

In most of the cases of pyosalpinx and suppurating tubo-ovarian cysts the tumours were so bound down by adhesions that during removal they burst, allowing the purulent contents to escape into the peritoneal cavity. Whenever this occurred the abdomen was thoroughly flushed out with sterilised water. Ventro-fixation was performed either for old-standing prolapse or for retroflexion with adhesions binding the fundus down to the sacrum. The most difficult operations of the series were those for diseased and adherent appendages. The patients had had repeated attacks of peritonitis and they suffered more or less continual abdominal pain, so that they were chronic invalids. In these cases on opening the abdomen all the pelvic organs were usually found to be densely matted together; the tubes and ovaries were matted to one another, to the pelvic wall, and to the intestines, so that usually the greatest difficulty was experienced in their removal. The one case of ventral hernia was in a woman on whom I had performed ovariotomy five years previously when the abdominal walls used to be sewn up with one layer of sutures. Nowadays, by sewing up the peritoneum, the rectal sheath, and the skin separately, ventral hernia is prevented. Exploratory incision without removal of any organ was performed three times. One case proved to be extensive malignant infiltration, the second was chronic cellulitis in the left broad ligament, and in a third a tumour of the size of an orange (probably malignant) was found to be growing in the posterior wall of the bladder.

The results of abdominal section at the Chelsea Hospital

for Women by my colleagues and myself have been so excellent for the last few years that I propose describing in detail the method of procedure. In the first place, the members of the Council deserve the greatest praise for carrying out so thoroughly and at such expense the recommendations of the Medical Committee. They have given us a perfect operating-theatre, complete in all its details, but even more important than that is the fact that they have fitted up a sterilising-room, opening out of the theatre, with boilers, &c., by means of which all instruments, towels, operating-aprons, &c., are rendered completely aseptic so that every possible precaution is taken to prevent the patient being exposed to noxious germs. Given, then, the above surroundings and given a resident medical officer and staff of nurses thoroughly imbued with the vital importance of asepsis, it is not to be wondered at that our mortality is so very small. I will now make a few remarks on certain details.

1. *Preparation of the patient.*—The day before operation the patient's pubes and abdomen are shaved and are then well scrubbed with carbolic soap and a nailbrush, special attention being paid to the umbilicus; a layer of wool soaked in a 1 in 1000 solution of perchloride of mercury is then applied and kept in position by means of a many-tailed binder until the time of operation.

2. *Operator and assistants.*—The hands and arms up to the elbow of the operator and his assistants are thoroughly scrubbed with soap and a nail-brush and then dipped (for at least a minute) in a 1 in 2000 hot solution of perchloride of mercury. A basinful of the same solution is kept at each side of the operating-table so that if during the operation the hands get fouled they can be rinsed in the solution. Personally I always prefer if possible that no other fingers than my own shall enter the peritoneal cavity.

3. *Instruments.*—Just before each operation the special theatre nurse sterilises all the instruments which are likely to be required. They are transferred from the steriliser direct to a glass tray containing plain-boiled water. If during the operation an instrument has to be got from the air-tight instrument-case the nurse at once sterilises it before handing it to the operator. The silk (I use nothing else) after being thoroughly sterilised is kept ready for use in glass bottles full of carbolic solution.

4. *Sponges.*—Although some operators use pads of aseptic wool sewn in gauze bags, I prefer sponges thoroughly cleansed, as they are less irritating to the intestines. During the operation they are simply wrung out of hot sterilised water, and of course if used in purulent cases or where the contents of an ovarian cyst consist of dirty grumous material, they should be destroyed directly after, but in these cases the gauze pads are best as they are inexpensive.

5. *Flushing.*—In all cases where a cyst with purulent or unhealthy grumous contents bursts during the operation I flush the peritoneal cavity thoroughly with plain sterilised water at a temperature of 110° F. but in no other cases. In operations on ruptured tubal pregnancies, after removing the large blood-clots with the hand and carefully mopping out the pelvis with a sponge on a pair of long forceps, I do not flush the peritoneal cavity unless the patient be very collapsed from loss of blood; then the flushing acts as a stimulant.

6. *Drainage.*—Some years ago I used to employ drainage frequently by means of a glass tube. Now I hardly ever drain, unless there be oozing from torn extensive adhesions low down in the pelvis on which a ligature cannot be put and the application of pressure forceps for a few minutes does not stop the oozing. I am confident that it is of the greatest importance to control all oozing before closing the peritoneal cavity and I do not hesitate to prolong the operation somewhat with that object. Drainage is not necessary after flushing out, but whenever it is employed the drain should be a piece of indiarubber tubing or iodoform gauze in those cases where some pressure is required to stop oozing. The drain should, if possible, be removed after 24 hours, though in some cases it might have to be left in for two or three days.

7. *After-treatment of the patient.*—In cases of hysterectomy which are accompanied by a good deal of shock, and in cases where the patients are feeble or collapsed, a nutrient enema of two and a half ounces of beef-tea and half an ounce of brandy should be given within an hour or two and repeated every four or six hours. Nothing is given by the mouth for 24 hours unless there be no sickness and the patient craves for some fluid. She may in that case commence six hours after to take a teaspoonful of hot water every hour. Where the sickness and retching are very persistent and troublesome the administration of half a pint of hot water with 20 grains of bicarbonate of soda dissolved in it will often act most beneficially. Opium in any form should, if possible, not be given. After 24 hours nourishment can be taken (provided there is no sickness). Most patients crave for a cup of tea (about four ounces) with plenty of milk, and every hour afterwards half an ounce of equal parts of milk and hot water can be given. When the sickness continues I stop everything by the mouth and feed per rectum.

The two great dangers after abdominal section are, in my experience, shock and tympanites from intestinal paralysis. The shock is combated by hypodermic injections of three minims of solution of strychnia three times a day. For tympanites my plan is to try to prevent its occurrence by having a soft rectal tube passed up the bowel every four hours, and if after 24 hours flatus is not freely passing (either naturally or by the tube), an enema containing an ounce of oil of turpentine to a pint of hot water is injected high up and, if necessary, is repeated two or three times a day. Once the escape of flatus is satisfactorily established my mind is at rest and the patients almost invariably do well. Nowadays the onset of peritonitis after abdominal section should be practically never met with, unless some unavoidable occurrence (such as the rupture of a pyosalpinx) has happened during the operation, and even then with careful and thorough flushing out the risk is small. I am not a believer in the efficacy of saline aperients, either for tympanites or peritonitis; they certainly have not proved in my hands anything like so effectual as the turpentine enemata.

Such are the methods which were adopted in the series of cases just recorded, but I cannot conclude these cursory remarks without expressing my warmest thanks to my colleague, Dr. Ewen J. Maclean, for his valuable assistance at the operations; to our most excellent and energetic resident medical officer, Dr. Victor Bonney, who was unsparing of himself in his devotion to the after-treatment of the cases, and who, after two years as an indefatigable and courteous officer, is leaving the Chelsea Hospital for Women in order to take up another sphere of work to the great regret of every member of the lay, medical, and nursing staff; and, lastly, my thanks are cordially given to the matron (Miss Heather Bigg) and to the nurses for the excellent manner in which they always perform their important duties.

Note.—Since the above was written there are eight more cases to be added to the list, making altogether 108 successful cases.

Harley-street, W.

SUPPURATIVE PERITONITIS; SPONTANEOUS EVACUATION; RECOVERY.

BY JAMES R. WALLACE, M.D. BRUX., F.R.C.S. IREL.,
SURGEON TO THE HOME HOSPITAL, CALCUTTA.

THE patient was an English girl, four years of age, who was admitted into the Home Hospital on Feb. 18th, 1899, suffering from febrile symptoms, intestinal pain, and diarrhœa, with fœtid evacuations. She was pale, emaciated, and had a marked cachectic appearance. She had suffered now and then from a low form of intermittent fever and occasional diarrhœa, and had been under my care four or five times. On admission the abdomen was found to be tense, tympanitic, and tender. the skin was hot and dry, the temperature was 102° F., and the face was pinched and anxious-looking. The child was peevish and she cried a good deal. Her bowels were relaxed, the motions being watery, slate-coloured, and very fœtid; they consisted of mucus and serum, somewhat fæcal stained; there was a slight cough, but the lungs were quite clear. Urine was passed freely and was of a natural colour. She was given castor-oil emulsion containing two drops of terebene and one of laudanum every four hours, alternated with five drops of mercuric bichloride solution (British Pharmacopœia) in water every four hours. The body was sponged with tepid water every six hours to reduce the

temperature. The abdomen was smeared with belladonna suspended in glycerine. Her diet consisted of raw arrow-root (a teaspoonful of the flour in a wineglassful of water) alternated with strong beef-tea every two hours. Within three days the intestinal fœtor had disappeared, the temperature had fallen to 100°, and the child was discharged from the hospital, at the mother's request, on March 5th, 15 days after admission. She seemed very much improved in condition and was able to walk about, though there was still tenderness on pressure in the umbilical area. Three days later the mother brought her into hospital again, as the fever had returned accompanied by severe abdominal pain and tenderness on pressure. It was now noticed that the umbilicus bulged a good deal forward, and on palpation distinct fluctuation was apparent quite two inches around the umbilicus. The temperature was 101°. A condition of subacute general peritonitis, probably tuberculous in origin, with effusion tending to suppuration, was diagnosed, and laparotomy was recommended. Colonel Havelock H. R. Charles, I.M.S., Professor of Clinical Surgery to the Medical College Hospital, saw the little patient on March 9th. He concurred with the diagnosis and plan of treatment and it was decided to open the abdomen on the following day. As a preparation for it the abdomen was thoroughly cleansed and a layer of sterilised boric cotton was used as a protective over the abdomen and kept in position by a binder of iodoform gauze. On the next day, after removing the binder and cotton dressings, a small portion of the latter was found to be adherent above the umbilicus, and in the effort to remove it the tissue beneath peeled off, and instantly a stream of pus welled up in a jet, quite six inches high, and flowed for about three minutes, till no less than 24 ounces had escaped. It was perfectly healthy in colour and devoid of shreds or clots or flocculi. Gentle pressure over the abdominal wall seemed thoroughly to empty the peritoneal cavity of its purulent contents, and when this was effected the spontaneous aperture above the umbilicus was dusted with iodoform and dressed with boric wool and iodoform gauze. There was immediate improvement in the child's general condition, there being no further rise of temperature, no pain, and no further evidence of the intestinal disturbance. The appetite improved and the child slept and ate well. There was no soaking of the dressings up to the fourth day, when they were removed and the child was made to wear a light flannel binder for another week. She gained flesh rapidly, and in a fortnight she was able to get about as briskly and gleefully as though she had not been ill at all. She was discharged from hospital on March 27th—i.e., 17 days after the spontaneous rupture of the abdominal wall. It is now nearly 14 months since she left the hospital and she has not had a day's illness during this time. When I last saw her—i.e., on May 8th—I was struck with her remarkably healthy and robust appearance. This case would seem to corroborate the modern belief that tuberculous peritonitis is curable by laparotomy and aseptic irrigation, on the theory that while in the one instance the morbid products are removed by direct lavage, in the other, as in this case, the degenerated tuberculous matter was completely thrown off in the form of healthy pus.

Calcutta.

CONTAGIOUS CATARRH OR ROUP IN FOWLS, AND DIPHTHERIA IN MAN.

BY J. GORDON SHARP, M.D. EDIN.

Distinction between gapes and roup.—Two diseases of fowls—namely, "gapes" and "roup"—are often confounded, but the two are distinct and at the outset I must make this point clear. Gapes is caused by the presence of a nematode worm—*syngamus trachealis* (*sclerostoma syngamus*)—in the windpipe. The disease is found not only in the domestic fowl but also in the lapwing, the magpie, and the pigeon. The disease receives its name from the gaping attitude assumed by the affected animal. The eggs of the worm probably live in the soil. Gapes does not further concern us at present. Roup, on the other hand, probably depends on a micro-organism. This, then, is the disease or diseases which especially concern us at present. I say "disease or diseases," for it is not possible to say definitely whether the name "roup" covers only one or more than one disease. The name is given to a condition common among poultry, especially among those which are kept in towns and in overcrowded, damp, and badly ventilated hen or poultry runs. So far as I am aware very little has been written on the subject from the scientific standpoint although every hen-keeper possesses a specific for the condition which generally fails to cure his own birds, however successful it may be, or may have been, with the birds of others. The name of the disorder would appear to be given because of the peculiar sound which the bird emits, although my observations lead me to the view that the sound only appears in the cases in which the disease attacks the windpipe. In such a case the sound may be due to the air passing over the fibrinous exudation. Where the membrane occupies the mouth only or the mouth and alimentary tract no such sound is heard. The sound is a rough rasping one and the name "roup" describes it very faithfully. The laity describe a "dry roup" and a "wet roup." Dry roup is commoner in old birds and is not very fatal, while wet roup is commoner in young birds and is highly fatal. Dry roup answers to the condition in children spoken of as "croupy," while wet roup may resemble membranous croup—at least, it does so in its effects. Roup further resembles diphtheria in that it may kill with great suddenness, and epidemics of roup, like epidemics of diphtheria, vary in severity and malignancy. At one time we find that the disease breaks out in a coop and attacks only two or three birds and the deaths may be limited, while no other coop in the neighbourhood is marked out for attack. The next epidemic may be as severe as the former was mild and all save the old birds may be cleared out in the course of a week and the disease may spread to all the coops in the neighbourhood and be equally fatal. Roup is most common in autumn and spring but may be prevalent at other times provided the weather be mild and moist.

A short history of some epidemics.—In 1893 I had experience of the disease in a district where outbreaks occasionally occur and where likewise diphtheria in the human subject is endemic or almost endemic. Here the disease was confined to one hencoop, which was completely cleared out by it. The disease did not spread, but this may be due to the fact that the house was removed some distance from others. The owners of the fowls did not have diphtheria, but diphtheria did appear in the nearest houses to this particular house. This is all one can say. I may here say something about the character of the soil of the district. The surface soil is made up of a sandy loam, while the soil and subsoil consist of a bed of permeable clay.

In the same district in June, 1895, there was an extensive outbreak of roup. 57 hens and chickens died in one yard, 27 in another, 15 in a third, and 15 in a fourth, besides large numbers in other yards, but as I am not sure of the exact details I mention no numbers. These coops were all within a radius of half a mile and the disease started at the foot of a rising ground and slowly spread upwards. How far the disease might have spread it is impossible to say had not the various proprietors disposed of the remaining healthy birds and whitewashed their henhouses and left them untenanted for several weeks. In one of the families at least severe cases of sore-throat occurred, but I could not say that it was diphtheria. Soon after this outbreak among the fowls—but certainly after the epidemic had ceased—two or three cases of true diphtheria were seen in the families of those who had possessed affected animals. For the present I make no deductions, I merely state the facts.

So far I have been reasoning from roup in fowls up to diphtheria in man and for a moment I turn to consider the converse, or the relationship of diphtheria in man to roup in fowls.

In the district already mentioned during 1899 there was an extensive outbreak of diphtheria affecting both children and adults. The epidemic started at the end of January and extended into February, when it abated till the middle of June and continued till the end of December. During all this time, I think I may safely say, not a single case of roup occurred in the area covered by the diphtheria outbreak.

In 1896 I investigated another limited outbreak of roup which took place in another district removed some four miles from the one already mentioned. The owner had about 20 hens, several of which had died during the past two months. The disease had spread to the neighbouring hen-run (divided by a high brick wall), but I failed to get an examination of the fowls in this yard. None of the members

of the family had suffered from sore-throat, and diphtheria was hardly known in the district.

Later (in 1896) I inquired into another outbreak of roup in this district. In this outbreak hens and pigeons were attacked and the death-rate had been high and chiefly among young birds. None of the family had suffered from sore-throat and diphtheria was hardly known in the district.

Morbid anatomy.—The following particulars may be taken as typical of the conditions found in all the outbreaks. One bantam hen standing about, or walking lazily when aroused, I examined carefully. The mouth was red, swollen, and highly inflamed, and at the angle on one side was a piece of sloughing tissue which I removed, and part of which I examined under the microscope after staining with picro-carmine solution. The epithelium was healthy in some parts, while in others it showed a granular disintegration. Large cells with one, two, or three nuclei were also seen in the field and some of the cells showed nuclei almost extruded. The mouth contained on certain parts of its surface a fine membrane, a bacteriological description of which follows. The bird from which these specimens were obtained had a very unhealthy appearance, but it emitted no roupy noise. In another hen-run one bird which made a very roupy noise was examined. The mouth was congested and covered with a whitish sticky membrane. The entrance to the air-passages was deeply congested and swollen and this latter probably accounted for the roupy noise. In other birds the membrane was tough, whitish-grey, and possessed a foul odour; in others the mouth, nostrils, gullet, and entrance to the windpipe were deeply injected and were covered by a yellowish tough membrane; in others, again, the eyes appeared to suffer severely. In none of the cases was any paralysis observed, but this may have been owing to the rapidity of the fatal result.

Bacteriology of the membrane.—Without entering into details one may say that a micro-organism was found which after the most careful observations could not be distinguished from the Klebs-Löffler bacillus. But it cannot have been a virulent microbe, for the persons handling the affected fowls and without any special precautions did not directly contract the disease. This is an important point, for although, morphologically, the microbe isolated could not be distinguished from the micro-organism of true human diphtheria yet it did not seem to set up the disease in those brought into close contact with it. Further, it must be stated that a bacillus resembling the Klebs-Löffler micro-organism has been found in the mouth of healthy fowls.[1] On the other hand, it must also be stated that according to many reliable observers the Klebs-Löffler bacillus (or one morphologically indistinguishable from it) is often found in the throats of perfectly healthy people.[2]

Conclusions and deductions.—1. Roup-like diphtheria (including the somewhat indefinite term "croup") varies in its malignancy, sometimes being mild with only one or two deaths in a large hen-run, while the next epidemic may almost clear out the whole coop. 2. The disease does not appear to be transmissible to man, for those handling the affected birds without any precautions do not suffer from any disease resembling diphtheria. 3. Paralysis was, according to my observations, absent in roup cases. 4. The disease is evidently a highly contagious catarrh and may correspond to the *morve* or fowl glanders of the French.[3] 5. Roup probably differs entirely from "fowl diphtheria," so called. 6. As we have already seen, bird fanciers distinguish between a "dry" roup and a "wet" roup. Dry roup is most likely a simple benign catarrh corresponding to the recurring croup affecting children, especially those inhabiting valleys and near a river bank. Wet roup, on the other hand, in its malignancy resembles diphtheria and membranous croup. 7. The micro-organism of roup (the wet variety or malignant variety) probably lives for a considerable time at least in the earth near the surface[4] and thus it is readily spread from animal to animal (as well as by direct contact with affected birds). 8. Conditions of soil and surroundings favourable to the spread of diphtheria would likewise appear to favour the spread of roup in fowls.

Leeds.

[1] Dr. Allan MacFadyen and Dr. Hewlett, Brit. Med. Jour., April 21st, 1900, p. 994.

[2] Park and Beebe, quoted by Osler, Principles and Practice of Medicine, second edition, pp. 103 and 104. O hers have also discovered the microbes in throats which were apparently healthy.

[3] M. Gallez fils made a report to the Belgian Academy of Medicine on "The Relation of Diseases of Fowls to Diphtheria." I have not seen the report itself but the following summary of it is given in THE LANCET of April 18th, 1896, p. 1082: "There are two perfectly distinct diseases to which such birds as domestic fowls are subject. First a contagious catarrh, called also *morve* or fowl glanders, characterised by a glairy secretion from the mucous membrane of the mouth, nostrils, and eyes, and also by rapid emaciation and paralysis of the legs. It is very contagious and very fatal and may give rise to diphtheria in the human subject. Its primary cause is a bacillus similar to Löffler's but far less virulent. ..... This disease differs from the second one which is known as fowl diphtheria both in its symptoms and in its etiology but has nothing corresponding to human diphtheria except its name."

[4] I found the Klebs-Löffler microbe (or one indistinguishable from it) in organically laden soil (see Brit. Med. Jour., August 22nd, 1896).

HYDATID CYST IN A NATIVE OF INDIA.

BY W. J. BUCHANAN, B.A., M.B. DUB.,
MAJOR I.M.S.; SUPERINTENDENT, CENTRAL JAIL, BHAGALPUR.

THE following case is published not on account of any clinical interest which it may have, but solely to put on record the fact that hydatid cysts are found, though very rarely, in natives of India who have never left their homes.

A native of the district of Bhagalpur was sent to jail in August, 1896, pending trial for rioting and murder. He complained at once of fever and pain in the right side and was admitted to hospital. On examining him I discovered a large abscess-like tumour in the right flank. No point of fluctuation being found I put in an aspirator needle and evacuated about a pint of highly fœtid thin pus-like fluid. The cavity of the cyst or abscess was then laid open, drained, and washed out with antiseptic lotions. In spite of this the patient did not improve and his temperature remained high (from 102° to 103° F.) up to the time of his death two days after. Death, I believe, was due to septic poisoning from the contents of the suppurating cyst. The abscess did not communicate with the peritoneal cavity.

The post-mortem examination made a few hours after death showed a large abscess cavity extending from the mid-axillary line, below the costal arch, up to the spinal column. All the other organs were found to be normal, but on removing the liver a yellow-white patch of cartilage-like colour was seen on the upper diaphragmatic surface of the right lobe of the liver. On cutting into this a considerable quantity of thin clear limpid fluid poured out containing numerous small cysts of a mother-of-pearl colour. The parent cyst was about as large as an infant's skull. Recognising it to be an hydatid cyst and knowing the extreme rarity of this affection in natives of India I did not further disturb the parts, but sent the liver to the professor of pathology at the Medical College, Calcutta, Dr. F. J. Drury, who reported to me as follows: "It is undoubtedly an hydatid cyst, containing a number of daughter and granddaughter cysts and numerous degenerated scolices." The abscess appeared to me to be a cyst which had suppurated. No cysts were found in any other organ.

Though not unknown, it is very rare to find this disease in India. Several cases have been recorded, but generally in Europeans or natives of India who have lived for some time in other countries. There are four specimens in the Calcutta Medical Museum, two from Europeans and two from persons of unrecorded nationality. Dr. Drury found hydatids post mortem in the body of an Eurasian who had lived in Australia. The Lahore Medical College Museum also contains a few specimens, but the nationality of the patients from whom they were taken is not known. Chevers[1] writes: "Our only evidence that hydatid disease can *originate* in India rests upon the debatable case of a low caste woman of Bhopal (Central India) who died with hydatids of the spleen." In this case, the woman being of the "sweeper" caste, who take care of and feed dogs, it is easy to understand the source of infection. Other cases are cited by Chevers, but in none of them is there clear evidence that the disease could not have been acquired out of India. It is this point which gives special interest to the present case, for I have ascertained from the deceased patient's family that *he never left his native home* except for a few months some years ago when he worked at the Raneegunge coal-mines in a neighbouring district.

The comparative exemption of natives of India from hydatid disease is strange as Dr. Cleghorn many years ago proved that tænia echinococcus very frequently occurred in cattle and sheep slaughtered for food in the Punjab. The same writer even started a theory that many cases of liver

[1] Diseases of India, p. 624.

abscess *might* be due to suppurative changes in hydatid cysts previously existing in the liver. This, however, has never been proved. Davidson in his "Geographical Pathology" makes no mention of India in his account of this disease and, strangely, the articles in Quain's Dictionary on this subject give no details as to the distribution of the parasite. The above case, however, proves beyond a doubt that hydatid cyst can occur in a native of India who has never left his own country.

Bhagalpur.

NOTE ON A NEW MEDIUM FOR THE GROWTH AND DIFFERENTIATION OF THE BACILLUS COLI COMMUNIS AND THE BACILLUS TYPHI ABDOMINALIS.

BY ALFRED THEODORE MACCONKEY.

(*From the Thompson-Yates Laboratories.*)

IN this medium advantage is taken of two well-known facts: (1) that the salts of bile are precipitated by acids, and (2) that bacillus coli communis produces acid in the presence of lactose while bacillus typhi abdominalis does not. The composition of the medium is sodium glycocholate,[1] 0·5 per cent.; peptone, 1·5 per cent.; lactose, 0·3 to 0·5 per cent.; agar, 1·5 per cent.; and tap-water, q. s. The lactose is added after filtration.

If stab cultures be made in this medium with bacillus coli communis and bacillus typhi abdominalis and incubated at 42° C. for from 24 to 48 hours it will be found that the tube inoculated with bacillus coli communis has become cloudy while the tube containing bacillus typhi abdominalis remains quite clear. If glucose be used instead of lactose both tubes become cloudy, but the cloudiness due to bacillus coli communis begins from below and that due to bacillus typhi abdominalis from above. In plates made with the glucose medium incubated for 48 hours at 42° C. and then left for from three to four days exposed to the light at room temperature the colonies gradually become orange coloured.

Though my experiments are not quite concluded I venture to draw the attention of bacteriologists to this medium because it has a more marked inhibiting effect than carbolised media upon the growth of ordinary soil and water organisms and may prove useful to those who are engaged in examining water, soils, and food-stuffs.

[1] The sodium glycocholate was supplied by Messrs. Baird and Tatlock and is, I understand, a mixture of the glycocholate and taurocholate.

THE EPILEPTICS AT WITHINGTON.—The Chorlton Board of Guardians are not at ease about the sane epileptic patients in their charge. From want of accommodation they are at present compelled to occupy the same wards as the imbecile and insane patients. This is obviously a state of things that should be remedied as soon as possible, for to some sane people, even though paupers, such association would be absolutely cruel. Dr. Rhodes said that the guardians were not responsible and that the blame should be laid on the Local Government Board who "were in default through their delay in giving sanction to the scheme which would make provision for these unfortunate people." Other places had the same complaint to make. Few will be found to contradict his further statement that "the methods of the Local Government Board were far too slow." He said he called a few days before at their offices and complained of the manner in which the Board treated the guardians, giving quite "a bit of his mind" to the, no doubt, astonished officials—i.e., if they could be astonished, for by this time such complaints must have lost all their novelty. "He considered the present methods of the Local Government Board were neither satisfactory nor even courteous to the guardians and were certainly not creditable to the former authority. He hoped the guardians would not further delay the provision of the additional accommodation at Withington workhouse. The treatment of epileptics was a matter concerning not merely the guardians of the Chorlton Union but almost every board in the country."

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ROYAL FREE HOSPITAL.

A CASE OF OBSTRUCTION DUE TO NEW GROWTH OF THE SIGMOID FLEXURE; INGUINAL COLOTOMY, FOLLOWED LATER BY RESECTION OF THE GROWTH; RE-ESTABLISHMENT OF THE INTESTINAL TRACT; RECOVERY.

(Under the care of Mr. W. H. BATTLE.)

AT the present day the treatment of malignant growths of the large intestine presents a very great contrast to that which was recognised as advisable even a few years ago. We seldom receive any intimation that a malignant growth is forming in the colon until symptoms of subacute or chronic intestinal obstruction arise. When such a case presents itself what treatment should be followed? Twenty, or even ten, years ago it was customary to remain satisfied with the performance of a colotomy, no attempt even being made to interfere with the primary cause of obstruction. At the present time much better results are obtainable. If the symptoms of obstruction are very severe a preliminary colotomy may be advisable, but in the less acute cases by far the best treatment is to resect the affected portion of bowel and re-establish the intestinal channel.

A man, aged 41 years, was admitted into the Royal Free Hospital on March 11th, 1900, complaining of intestinal obstruction. A fortnight before admission he had severe pain all over the abdomen and on March 1st his bowels were opened, but there had been no motion since, though some flatus had passed. As the abdominal pain steadily grew worse he took to his bed on the 4th. He was treated by a medical man but the pain did not abate. On the 6th vomiting commenced and had continued at intervals; he described the vomited matter as resembling coffee-grounds. He had been able to take nothing but milk and water since the 5th. There was nothing remarkable in his family history.

On admission the patient looked thin and ill; the abdomen was distended and tympanitic on percussion, but no distinct swelling could be made out and no peristaltic movements were visible. On examination per rectum nothing abnormal was discovered. Obstruction of the large bowel was diagnosed and, in the absence of Mr. Battle, Mr. T. P. Legg, the senior resident medical officer, decided to operate.

The skin of the abdomen having been washed and the patient anæsthetised an incision three inches long was made at right angles to a line drawn from the umbilicus to the anterior superior iliac spine, one-third of the distance from the spine, with the centre of the incision on the line. The incision was deepened until the peritoneum was reached; when this had been incised the large intestine was found and the sigmoid flexure was drawn out into the wound. The bowel was greatly distended and was secured to the edges of the wound by two stitches which did not penetrate the intestinal wall. Another stitch drew together the edges of the incision under the bowel, passing through the mesentery; this was in order to form a well-marked spur. The bowel was then covered with protective and gauze and the wound was dressed. On the next day the patient felt a little better and had no vomiting, but the bowels did not act. On March 13th he vomited a little. The intestine was opened and a Paul's tube was inserted for drainage; his temperature had not exceeded 100° F. Much fæcal matter came away, but he vomited no more. The patient's condition steadily improved and the wound looked well. By April 5th he was allowed to get up every day.

On April 6th Mr. Battle decided to explore the abdomen for the purpose of discovering the cause of the obstruction and removing it if possible. The skin having been cleansed

Mr. Battle made a median incision, four inches in length, between the umbilicus and the pubes; the recti were separated and the peritoneum was incised. The operator's hand was then introduced and a hard mass was felt at the lower part of the sigmoid flexure, with some scattered hard mesenteric glands. The growth was brought outside the wound and as it was distinctly limited it was decided to remove it. The wound all round the exposed piece of bowel was packed with gauze and clamps of rubber-tubing were passed through holes in the mesentery and fastened with pressure forceps; two of these clamps were placed on each side of the growth and an inch apart. The bowel was then divided with scissors between each pair of clamps and the growth with some of the corresponding portion of mesentery was removed. There was some amount of hæmorrhage during the division of the mesentery, but it was soon stopped with pressure forceps. The divided vessels were then tied and the wound was packed afresh with gauze and the cut ends of the bowel were washed. These ends were then inverted and sewn up with Lembert's sutures. The pieces of bowel were then placed side by side with the ends in opposite directions and so placed that the posterior aspect of one piece lay against the anterior aspect of the other. Then the serous coats were united by continuous Lembert sutures for two inches in the long axis of the bowel, the ends of the silk being left long for future use. An incision of two inches in length was made in each piece of bowel parallel to the seam and passing through all the coats of the intestine. The adjoining edges of the incisions were united by continuous sutures passing through the mucous and muscular coats. Then a needle was threaded on to the long end of silk left from the first seam and the remaining portion of the suturing of the serous coat was performed by Lembert's method. The bowel was washed and replaced in the abdomen. The abdominal wall was then closed in successive layers and the wound was dressed with cyanide gauze. A length of about six inches of the bowel was removed. On section it was found that the lumen was almost closed; it proved to be a columnar-celled carcinoma.

The patient did well after the operation and free escape of fæcal matter occurred from the rectum through a tube which had been placed there to prevent any accumulation. He steadily progressed and on April 23rd a curved piece of wood covered by rubber tubing was introduced into the colotomy wound to press on the "spur." It caused a little pain, but the spur became much less obvious. The bowel was washed out daily both through the anus and through the colotomy wound. He was allowed to get up every day. On May 5th a different instrument was employed to exert pressure on the spur and in a few days solid motions were passed through the rectum. On May 15th Mr. Battle decided to close the colotomy opening. After the patient was anæsthetised and the skin around the wound had been washed an oblique incision was made above and another below the opening, and these were then joined so as to surround the artificial anus. By careful dissection the edges of the opening were dissected up without opening the general peritoneal cavity. Then the opening in the mucous membrane of the bowel was closed with 16 silk interrupted sutures. The sub-peritoneal tissue was united over the stitches and the muscles and skin were sutured separately. A drainage-tube was inserted.

After the operation the patient progressed satisfactorily. A small quantity of pus escaped for a few days from the tube and after the latter was removed a small collection of pus was found and opened, but later the wound healed and on March 5th the patient left the hospital completely recovered. He was seen at the hospital on June 29th, having recently returned from a convalescent home. He looked bronzed and well, having gained seven pounds in weight during his stay at the home. The bowels acted regularly and without difficulty; there was a small sinus in the site of the former colotomy opening from which there had been a little fæcal-smelling discharge.

Remarks by Mr. BATTLE.—On account of the distension of the abdomen and general condition of the patient no search was made for the cause of the obstruction when colotomy was performed. It appeared probable that this cause was a malignant stricture of the large bowel, probably the upper part of the rectum or sigmoid flexure, and it seemed a pity to let a man with the possibilities for further usefulness of this patient pass out of observation condemned to the life of an invalid, with a prospect of death in a few months from extension of growth to other parts, when it might be possible to lengthen life by removal of the growth and make it much more comfortable by a lateral anastomosis and closure of the colotomy wound. The details of the case do not differ much from those given in the description of similar cases treated in this way by me, and I need not refer to them. The apparatus made for getting rid of the spur is perhaps of interest, as it has proved useful. It consists when completed of a T-shaped instrument which can be easily made in the wards without special apparatus. Two pieces of ordinary firewood are taken, a long one (about three inches in length) and a short one (about two inches). The long one is drilled longitudinally through its centre by means of a red hot skewer; the short one is shaped like a bow. Both are covered with drainage tubing, a double piece of thread encircling the smaller is carried from its convex border up the centre of the longer one. The smaller piece is then placed astride the spur of the colotomy opening and the long arm is fastened to it by pulling on the string which is secured so as to complete the T. Pressure is applied by means of the dressings and body bandage. It is inexpensive, easily made, permits fæcal matter to pass it, and effectively acts on the spur. I have tried other methods of getting rid of the spur after colotomy, but none have given me quite such satisfactory results.

GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

A CASE OF PNEUMONIC PLAGUE TREATED BY LARGE DOSES OF CARBOLIC ACID; RECOVERY.

(Under the care of Mr. J. BELL, Assistant Superintendent.)

As we have on some previous occasions pointed out, carbolic acid is much less poisonous than it is usually considered to be. The toxic symptoms which appear when the drug is taken in an undiluted form are almost entirely referable to the local caustic action. When taken with free dilution phenol gives rise to very few symptoms indeed; in many cases even the darkening of the urine ("carboluria") may not be present. With regard to the question of its therapeutic value in plague, it is as yet impossible to from an opinion, and we await with much interest the result of the extended trial of carbolic acid in the treatment of plague which Mr. Bell tells us he is carrying out.

A healthy Greek sailor, aged 24 years, was admitted into the Government Civil Hospital, Hong-Kong, on April 17th, with gonorrhœa. His temperature was 101°F. and save for the local condition he seemed to be well and made no complaint. His temperature for the next two days kept slowly rising and his tongue became more furred till the morning of the 20th when he was very apathetic, the temperature being 105° and the tongue very dry and furred; there were no buboes. The principal civil medical officer (Dr. J. A. Lowson) now saw the patient and agreed that there was a probability that he was suffering from plague. His lungs were full of coarse râles all over, but there was no dulness. Shortly after the consultation he began to spit thick bloody sputum, which on examination was found to be full of typical bacilli. As he was too ill to be moved to the Infectious Diseases Hospital he was at once isolated and put on a suitable diet with stimulants. Hypodermic injections of digitalis and strychnia were made every four hours and 12 grains of pure carbolic acid in solution were given every three hours. He continued to be very ill all day, the pulse was very quick and intermittent, he was delirious, and the temperature ranged between 105° and 106·4°. On the next day there was a marked though slow change for the better. His temperature slowly fell to 102° and only rose to 103·4° in the evening. The tongue was more moist, though it was still very furred, and the breath was offensive. Injections were not required so frequently as his pulse was stronger and not so quick, varying from 94 to 102. Bacilli were still in the sputum both morning and evening. His temperature slowly fell each day till the 24th, when it became normal. The sputum soon ceased to contain blood, though it was very free for 48 hours. His tongue remained moist and slowly cleaned and the patient expressed himself as feeling much better in every way. On the 24th there was no sputum and the lungs were quite clear. The carbolic acid was decreased after 48 hours to four hourly doses and was stopped on the 24th, from which date the patient convalesced rather rapidly. It was ascertained through his friends that he contracted the original trouble

at a house in the infected area some 14 days previously to his admittance to hospital.

Remarks by Mr. BELL.—This form of plague is extremely fatal and I know of no cure here. The case came under treatment early and he was a strong healthy patient, but the effect of the carbolic acid was most marked, and I report the case in the hope that others will at once try it, especially on Europeans, who come under treatment as a rule early. It is now being tried on every case admitted to the Plague Hospital, and as soon as 50 cases have been under treatment the results will be communicated. In all this patient had 280 grains of carbolic acid without any symptoms of poisoning by the drug. The original trouble for which he came to hospital was unaffected both by the plague and its treatment.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Bacteriology of Dysentery, Yellow Fever, and Diphtheria.—The Way in which Bones Break.—The Relation of Mosquitoes to Malaria.—The Composition and Action of Brown-Séquard's Fluid.—Neutralisation of Culture Media.

A MEETING of this society was held on June 30th in the Pathological Laboratories of the University of Cambridge by the invitation of Professor SIMS WOODHEAD, Dr. W. OSLER occupying the chair.

Professor SIMON A. FLEXNER (Philadelphia) made a communication on the Pathology of Tropical Dysentery. He said that an acute and a chronic form could be distinguished on clinical and pathological grounds. The acute form might terminate fatally in from 48 to 72 hours or it might be recovered from or become chronic. The chronic dysentery *per se* of the tropics was amœbic in nature. The acute variety was not caused by amœbæ; but from the stools a bacillus had been isolated differing from the normal intestinal flora and showing specific properties. It agglutinated with the blood serum of dysenteric cases. Its properties placed it very near the bacillus typhosus, from which organism it could be distinguished by biological and physiological peculiarities. The bacillus which was obtained from cases of dysentery occurring in and about Manila apparently was identical with an organism isolated by Shiga from the disease endemic in Japan. From a case of dysentery contracted in Puerto Rico the same organism had been obtained.

Professor FLEXNER also made some remarks on the Supposed Bacillus of Yellow Fever. The widespread fatty degenerations produced in the viscera in this disease were not special to this organism. Other organisms produced these changes and also hyaline necroses, just as the yellow fever bacillus did.

Dr. J. GRIFFITH (Cambridge) gave a demonstration on the Way in which Bones Break. He referred chiefly to the method of breaking by torsion. That was the easiest method of breaking a bone. He illustrated his remarks in the case of the femur, the ribs, and the clavicle and the tibia. A spiral fracture resulted from torsion. If the long axis of the bone was bent as well as twisted the spiral would be shorter.

Dr. GEORGE H. F. NUTTALL (Cambridge) gave a demonstration upon the Relation of Mosquitoes to Malaria. The demonstration consisted in the exhibition of the developmental changes undergone by avian and human parasites in species of culex and anopheles respectively, these being illustrated by means of specimens, photo-micrographs, and drawings. Living specimens of anopheles maculipennis, caught by Dr. Nuttall in the vicinity of Cambridge, as also of culex, were shown in tanks, and their biological characters were referred to. Maps showing the geographical distribution of malaria over the world and its former prevalence in England were exhibited, and the present geographical distribution of the genus anopheles, as far as was known, was described. A decided agreement between the former distribution of malaria in England and the distribution of anopheles (anopheles maculipennis, anopheles bifurcatus, anopheles nigripes) at the present time was observable. The studies regarding this distribution were, however, not as yet concluded. The development of human malarial parasites had been observed in nine species of anopheles in different parts of the world (India, Africa, Italy, and the United States), whereas all experiments made with species of culex, at least ten (in Italy, Africa, and India), had given negative results. Although it was quite possible that a species of culex might be found which was capable of serving as intermediary hosts to human parasites, the evidence hitherto gathered pointed solely to anopheles as fulfilling this function. The interesting fact that anopheles persisted in England whilst malaria had to all appearances disappeared was a subject for further investigation. The disappearance of the malarial parasites might very well be due to a progressive diminution in the number of anopheles, a plentiful supply of which was absolutely necessary for their continued existence. There might, however, be other factors concerned in their disappearance which still remained to be discovered. The suggestion that it might be due to the anopheles in England not sucking blood was untenable, for Dr. Nuttall had proved the contrary by experiments upon himself.

Dr. LOUIS COBBETT (Cambridge) showed some Cultures of Bacillus Diphtheriæ which had been obtained from the nasal discharge of a pony. The original culture was sent by Dr. Mearns Fraser, medical officer of health of Portsmouth, who while investigating the causation of an attack of diphtheria in a little girl had noticed that her father's pony was suffering from a purulent and slightly sanguineous nasal discharge. Experiments were described which established the identity of the bacillus. The horse had hitherto not been known, among animals, to suffer from diphtheria.

Dr. COBBETT also described experiments showing that Diphtheria Toxin was Excreted in the Urine, both from susceptible and from relatively insusceptible animals—e.g., the guinea-pig and the rat. From these animals, injected with diphtheria toxin, the urine secreted during the next few hours was collected with a catheter and injected subcutaneously into guinea-pigs. It produced an inflammatory swelling at the seat of inoculation, followed by dry necrosis, falling out of the hair, and in one instance death. Control experiments were made with the same urine to which a little antitoxin had been added. Other control experiments also were made with the urine of normal animals.

Dr. W. E. DIXON (Cambridge) made a communication on the Composition and Action of Brown-Séquard's Fluid. He gave an abstract of the results of experiments which he had performed by injections of orchitic extract of different animals. The composition of orchitic extract of all animals was practically identical. The active principles consisted chiefly of two bodies—(1) nucleo-albumin; and (2) spermine. The former he showed was very toxic, producing great cardiac inhibition reflexly through the cardiac nerve centres. The latter, spermine, which was also present in considerable quantity in semen, produced its effect principally by producing congestion of the abdominal viscera, including both the testes and ovaries.

Dr. J. W. H. EYRE made a communication on the Neutralisation of Culture Media. He remarked on the uncertainty of litmus paper and of litmus solution. He advocated a standard medium among English bacteriologists by the use of phenyl-thalein as an indicator of the alkalinity of culture media.

Votes of thanks to Professor Sims Woodhead and the University authorities and to those who had communicated their researches terminated the meeting.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens and Micro-photographs.—Suppression of Urine following Cystitis.—Cæsarean Section followed by Sub-peritoneal Hysterectomy.—Cleansing the Peritoneum during Cœliotomy.—Eclampsia treated by Saline Effusion and Veratrum Viride.

A MEETING of this society was held on June 27th, Dr. R. MILNE MURRAY, the President, being in the chair.

Professor A. R. SIMPSON showed (1) a Dermoid Cyst of the Ovary which formed the channel of a Fæcal Fistula; and (2) two Fibroid Uteri removed by Panhysterectomy.

Dr. J. LAMOND LACKIE showed an Early Extra-uterine Gestation.

Dr. J. HAIG FERGUSON showed a Uterus removed by Vaginal Hysterectomy for Cancer of the Cervix.

Mr. J. STUART NAIRNE (Glasgow) showed a Uterus with Placenta *in situ* removed from a Dwarf by Cæsarean Section at full term.

Dr. N. T. BREWIS showed (1) a Subperitoneal Fibroid

removed from the Uterus; and (2) an Appendix removed just on the point of bursting.

Dr. JAMES FOULIS exhibited Micro-photographs of Sections of the Embryo and Yelk Sac of the Deer showing the double layer of the amnion continuous with the somatopleure.

Dr. LAMOND LACKIE read a paper on a case of Suppression of Urine following Cystitis. The patient first came under observation eight years ago when she had all the symptoms of chronic cystitis. The usual treatment by irrigation, diet, and drugs was adopted without effect and the pain during micturition continued in an aggravated degree. The urethra was dilated by Hegar's bougies so that the bladder might be explored. This gave complete relief of all the symptoms, but, unfortunately, the patient never regained control over the act of micturition. By the aid of a portable urinal, however, she became fairly comfortable. Although repeatedly advised to do so she always refused to submit to any further treatment to cure the incontinence as she dreaded a return of her former symptoms. In March of this year Dr. Lackie was called to see her and was informed that except for some sickness she was quite well, but she had not passed any urine for nine days. Diuretics were given and hot-air baths were used with the result that 24 hours afterwards urine commenced to flow freely. For eight days the patient improved when suddenly excessive sickness set in and complete suppression of urine supervened. She had none of the usual symptoms of uræmia which are supposed to be always present in non-obstructive suppression. The patient gradually became comatose and died 48 hours after the onset of the second attack of anuria. Post-mortem examination showed that the bladder was reduced to the size of a small tube and that the right kidney was in a condition of acute septic nephritis, whereas the tissue of the left kidney was entirely replaced by tuberculous material. In conclusion Dr. Lackie discussed the literature of the subject.

Dr. N. T. BREWIS read notes of a case of Cæsarean Section followed by Sub-peritoneal Hysterectomy. It was performed at term for contracted pelvis. The patient was pregnant for the fifth time. Her first child was stillborn at seven months, delivery being brought about by forceps and great force being required to effect it. Two early miscarriages followed and then came a labour at full time which was completed by basilysis. The true conjugate measured from two and a half to two and three-quarter inches. The question of the particular operation to be adopted in this case was discussed. Symphysiotomy was out of the question because it had been premised that measures would be taken to prevent a future conception. One of the following operations might be chosen: (1) Sänger's Cæsarean section; (2) Porro-Cæsarean section; (3) Cæsarean section followed by panhysterectomy; or (4) Cæsarean section followed by sub-peritoneal hysterectomy. Dr. Brewis had performed the Porro operation some years ago in two cases and panhysterectomy four times for new growths between the fourth and sixth months of pregnancy with success. The latter operation was attended with no special difficulty and was as easily performed as the Porro operation. The subsequent risks of hæmorrhage and sepsis, he considered, were greater with the Porro operation. He would restrict Porro-Cæsarean section to cases where the patient was in an exhausted state and where the operator had not proper assistance, as it was an operation which could be done very quickly. He decided against improved Cæsarean section on account of the danger of the subsequent gaping of the uterine wound, hæmorrhage, and peritonitis, and because the patient was liable to all the risks associated with the puerperium. There was little to decide between Cæsarean section followed by panhysterectomy and that by subperitoneal hysterectomy. The latter method was selected owing to his having had experience of the technique in removing fibroids. In this case the child was born alive and the mother made an easy recovery.

Dr. N. T. BREWIS also read a paper on Cleansing the Peritoneum during Cœliotomy. Irrigation was now less frequently resorted to than formerly, as surgeons had more confidence in their technique and in the power of the peritoneum to dispose of fluids and minute solid particles and to resist the invasion of pyogenic bacteria. There was, however, special danger of peritoneal contamination in the bursting of a pyosalpinx, ovarian abscess, or similar condition during operation. In removing pus sacs of the appendages the patient was placed in the Trendelenburg position. On opening the peritoneal cavity numerous adhesions would probably be found between the omentum and pelvic organs, intestines, and parietal peritoneum. These being separated would be drawn up and packed off with gauze pads, so that the only part of the intestinal tract left in the pelvis was the rectum. The pus sacs could now be liberated and brought out through the abdominal wound. Careful handling was necessary to prevent rupture, and with this object the sac might be aspirated before it was drawn up. In this way the operator would in many cases be able to successfully remove the diseased parts without contaminating the peritoneum. But in spite of precautions pus would escape by rupture of thin walls or from swellings where its presence was unsuspected. Was the surgeon then to consider the pus sterile and unlikely to produce serious results and simply to trust to sponging; or was he to look upon the presence of even a small quantity of pus as dangerous and to do all in his power to get completely rid of it? Most surgeons adopted the latter view. The plan adopted should not spread the infection and the irrigation should thus be confined to the peritoneal area already contaminated. Care should be taken to prevent the water from flowing up among the intestines and distributing the infection. Whenever pus was seen to be escaping from a ruptured sac the part should be covered over with a large gauze pad. Then the general cavity of the peritoneum was carefully packed off and protected in a similar manner. The diseased structures were then removed. A long pair of forceps or blunt-pointed scissors were then passed into the vagina and their points were pushed through the posterior fornix into the pouch of Douglas; the opening was enlarged by separating the blades. The pelvis was then lowered and its cavity was irrigated from above by introducing the end of the douche through the abdominal wound. The stream of water or normal saline solution washed out the pelvis and escaped through the opening at the bottom of the pouch of Douglas into the vagina and out at the vulva. By this method there was no chance of infection being carried up into the general peritoneal cavity and it permitted of the most thorough cleansing.—Mr. J. STUART NAIRNE, Dr. F. W. N. HAULTAIN, Dr. J. W. BALLANTYNE, Dr. J. FOULIS, Dr. W. FORDYCE, and the PRESIDENT discussed the papers.

Dr. J. W. BALLANTYNE read a clinical note on a case of Eclampsia treated by Saline Infusion and Veratrum Viride. The patient was at the sixth month of her second pregnancy; her first had passed off normally without any appearance of dropsy or abnormal symptoms. For a week before the fits she had noticed that her urine was unusually pale and for a month she had suffered from some swelling of the legs. Shortly before the first fit she experienced a severe pain in the epigastrium followed by violent headache. The urine passed previously to the fit contained two-thirds of albumin and nothing was found on microscopical examination. The condition was treated with enemata of bromide of potassium and chloral hydrate and hypodermic injections of veratrum viride, and the convulsions were controlled by the inhalation of chloroform. A pint and a half of saline infusion were injected into the loose tissue below the breasts. Shortly afterwards the urine was drawn off by catheter, the patient being comatose, and was found to amount to several ounces; it contained blood and more than two-thirds albumin, with numerous epithelial and granular tube-casts. As the condition was grave it was thought advisable to procure abortion. This was done by inserting and leaving a bougie in the uterus; neither Champetier de Ribes's nor Barnes's bag would pass the internal os. Labour pains came on very slowly and the child was born on the next day. In all 18 fits occurred. The fits had subsided and the patient had regained consciousness before the labour had properly started. As the fœtus was born alive fœtal death could not be invoked as a cause of the cessation of the fits. The patient steadily improved and in a week the urine contained only a trace of albumin and in 16 days it was normal. An interesting point with regard to the urine was noticed. Specimens were preserved of urine passed before the onset of the convulsions, during the fits while the patient was comatose, after the delivery, and daily for the next four days. All were kept in corked bottles with no special precautions. Three weeks afterwards the last four were found to be alkaline in reaction and then showed signs of decomposition; later specimens showed more marked evidences of decomposition. The first three specimens, however, which were much older than the others, were still all acid; the first one, although acid, was now beginning to show slight signs of

decomposition; the second one, drawn off during the eclampsia, was quite undecomposed, although nearly a month in the bottle; and the third, which was also acid, was equally sweet.—In the discussion it was suggested that the non-putrefaction might be due to some special recondite substance in the urine associated with the occurrence of eclampsia and excreted by the kidney; also that it might be due to the presence of chloral in the urine, but the first specimen was obtained before any drug was given.—The PRESIDENT and Dr. FOULIS discussed the paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Dupuytren's Contraction of the Palmar Fascia.—Operation for Cleft Palate.—Truss Gauge.

A MEETING of this section was held on May 11th, Mr. R. L. SWAN, the president, being in the chair.

Dr. J. KNOTT read a paper on Dupuytren's Contraction of the Palmar Fascia. He had recently observed a series of cases in elderly soldiers, most of whom gave no history of local injury or irritation. One had suggested that the prolonged holding of the rifle had something to do with the flexion. One had received a bullet wound in the groove between the thenar and anti-thenar eminences of the right hand. The cicatrix was limited to this region, yet it proved the starting-point for the contraction of the whole palmar fascia, the condition afterwards developing on the left side, as it had done in all the cases which he had seen. He had recently met with two strikingly contrasted cases — one in a free-living man who presented the extreme degree of flexion in the ring finger, the little finger, and the middle finger of both hands; the other in a teetotaller, in whose case the deformity was but slight but perfectly typical. Dr. Knott looked upon the process as essentially of the nature of gouty or rheumatic-gouty inflammation. He had operated on two cases with a fair degree of success, but from the nature of the conditions he considered a "perfect cure" impossible in any case.—Mr. E. H. BENNETT remarked that he had the condition, which had developed in his right hand and was beginning to develop in the left also. He could appreciate the justice of the remark that it commences in the ring finger. Being a racket player he might attribute it to the irritation caused by the butt-end of the racket, but this explanation would not apply to the left side, and its symmetrical development therefore puzzled him. He had dissected many preparations, but could discover no satisfactory explanation of its causation.

Mr. TAYLOR described his New Operation for Cleft Palate, drawing special attention to the anatomical facts that the principal vessel distributed to the hard palate reaches it at its posterior part, having emerged from the posterior palatine foramen at the inner side of the alveolus of the last molar tooth, and that in the palate this vessel takes a curved course close to the alveolar border of the maxilla, its main offshoots proceeding towards the middle line from its inner concave border. He stated that his operation was essentially indicated for clefts of the complete variety—namely, those which advanced quite up to or near the teeth in front. For the operation the patient was put in Rose's position on a low operating table. A Smith's gag was introduced into the mouth, and the edges of the cleft were pared freely. Blood and saliva were removed by a suction apparatus and as far as possible sponging was dispensed with. A curved incision was made on each side close to the alveolar margin of the palate from the level of the last molar tooth behind, and terminating in front of the middle line behind the incisor teeth. The posterior palatine artery was thus included in the flap. The latter was reflected on each side by means of a rugine, and not by any of the various forms of raspatory which are usually recommended. The flap, thus completely lifted up from before backwards, was held back and the junction of the soft with the hard palate was divided with a knife or with a pair of curved scissors. Bleeding was easily controlled by digital pressure. Silkworm gut or silver wire was employed in bringing the edges of the flaps together and Mr. Taylor laid great stress upon the facilities afforded by the mobility of the flaps in carrying out this step of the operation. The free ends of the flaps in front were securely fixed to the tissue of the gum behind the incisor teeth, care having been taken in marking out the flaps to leave enough for this purpose. Should it be necessary a lateral incision might be made on each side at the junction of the hard and the soft palate, and at the inner side of the hamular process, so as to relieve tension and secure rest to the palate during the process of healing. — Mr. E. H. BENNETT, Dr. G. J. JOHNSTON, Mr. J. LENTAIGNE and others discussed the paper.

Mr. T. KELLY of Enniscorthy described the Truss Gauge, an instrument consisting of two overlapping steel truss springs. On the surfaces where this overlapping took place divisions were marked, and in each division there was a corresponding character or number. In the case with each set there was a bundle of cards with divisions printed to correspond to the division on the truss gauge, so that the necessary dimensions could be filled in and transmitted to the instrument maker.

SECTION OF ANATOMY AND PHYSIOLOGY.

Cranio-cerebral Topography.—Nasal Fossæ.—Configuration of the Heart.—Lymph Circulation.

A meeting of this section was held on June 1st, Professor D. J. CUNNINGHAM being in the chair.

Dr. E. H. TAYLOR read a paper on Recent Researches on Cranio-cerebral Topography conducted by himself and Dr. W. S. Haughton. They recommended the employment of the following landmarks, which were easily located and were of undoubted utility: the centre of the naso-frontal groove or nasion; the external angular process of the frontal bone; the depression immediately above it, or the orbito-temporo angle; the external auditory meatus; the pre-auricular point; the zygoma; the external occipital protuberance or inion; and a straight line connecting the nasion and the inion. The procedure adopted was as follows. Several subjects, of ages varying from one year to 60 years, were injected with a 10 per cent. solution of formalin. By this means the tissues were well hardened and could be readily cut *en bloc*. The head in each case was removed from the trunk and was divided accurately in the sagittal plane. The cerebral hemispheres were then removed, and this was easily done in consequence of the very firm consistency of the brain substance. Before removal, however, their exact position inside the skull was carefully noted. The pia mater was removed and strips of very soft and pliable tin wire were introduced into the principal fissures. The corresponding half of the skull was now brought down over the hemisphere, which, by its mesial aspect, lay on a smooth slab of glass. Skiagrams were then taken of each half of the head and this part of the investigation was conducted by Dr. Haughton. In all cases good views were obtained, and as the result of the information which they afforded a method was adopted for mapping out the principal fissures, of which the following is a summary. There are three fundamental fissures which it is necessary to localise, as they separate the four main lobes of the brain—namely, the fissure of Silvius, the fissure of Rolando, and the external parieto-occipital fissure. The distance between the nasion and inion is first carefully estimated and is divided into four equal parts. From the orbito-temporal angle a line is drawn to the junction of the third and fourth segments of this line (naso-iniac). It corresponds to the posterior limb of the Sylvian fissure for the greater part of its extent, and is, therefore, called the Sylvian line. The Sylvian point is the term employed to indicate the level at which the main stem of the fissure reaches the outer aspect of the hemisphere and divides into its anterior, vertical, and posterior limbs. It corresponds to the intersection of the Sylvian line with another drawn from the junction of the first and second segments of the naso-iniac line to the pre-auricular point. In certain of the heads examined it would have been more correct to have made this line terminate opposite the centre of the external auditory meatus. The posterior extremity of the Sylvian line overlies the external parieto-occipital fissure. This point represents 75 per cent. of the distance between the nasion and the inion. The general direction of the fissure of Rolando is found by connecting the two following points by a straight line. The upper point is on the middle line of the head and three-quarters of an inch behind the centre of the naso-iniac line, or as near as possible 55 per cent. of the naso-iniac distance. The lower point corresponds to the intersection of the Sylvian line with another line starting from the pre-auricular point and perpendicular to the upper

borders of the zygoma, or to a line connecting the centre of the infra-orbital margin with the centre of the external auditory meatus.—Professor CUNNINGHAM and Dr. DAWSON discussed the paper.

Dr. FAGAN gave a lantern demonstration of a series of normal and pathological Nasal Fossæ prepared to show the various parts of these cavities and their relations to the surrounding structures.

Dr. CHARLES J. PATTEN read a paper on the Configuration of the Heart in Man and some other Mammalian Groups. The communication dealt chiefly with the modifications in form which have taken place in the heart of man following the erect posture. In specially hardened specimens the conical shape of the human heart had almost disappeared. In many quadrupeds which carried the trunk prone the true conical shape of the heart persisted.

Mr. J. S. ASHE read a note on the Lymph Circulation, in which he advanced the view that one of the forces which helped to carry on the lymph circulation was the dilatation of the aorta which took place at each systole of the heart, pressing on the thoracic duct and increasing the pressure in the posterior mediastinum. His theory was illustrated by a schema which showed by means of elastic tubes the suggested effect of the dilatation of the aorta on the thoracic duct.

ULSTER MEDICAL SOCIETY.—The annual meeting of this society was held in the Belfast Museum on Thursday, June 21st, the President, Dr. James Graham, being in the chair. After the reading of the minutes the various reports were presented and passed. From these it appeared that there were seven meetings held during the past session with an average attendance of 36 members on each occasion. There are now 148 members on the roll of the society, and there is financially a balance in hand of over £55. The following office-bearers were then elected for the session 1900–1901:—President, Professor W. H. Thompson; Vice-presidents, Dr. E. C. Bigger and Dr. R. W. Leslie; Council, Dr. W. Calwell, Dr. H. McKisack, Professor Byers, Dr. John Campbell, Dr. A. Dempsey, and Dr. J. Colville; treasurer, Dr. John McCaw; pathological secretaries, Dr. J. Lorrain Smith and Dr. T. Houston; librarian, Dr. T. S. Kirk; secretary, Mr. Robert Campbell. A discussion took place on a report of a committee appointed by the North of Ireland Branch of the British Medical Association and the Ulster Medical Society in reference to the formation of an Ulster Board for the examination of nurses, but it was decided to refer the whole subject back to the councils of these two societies for further consideration. On the motion of Professor Byers a very cordial vote of thanks was accorded to the retiring secretary, Dr. James Colville, who for the past three years has devoted much time and attention to the affairs of the society.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following have been elected as office-bearers for the ensuing year:—President: Mr. John Ackery. Vice-Presidents: resident, Mr. W. A. Maggs, Mr. Arthur S. Underwood, Mr. F. J. Bennett; non-resident, Mr. J. Henry Whatford (Eastbourne), Mr. G. Brunton (Leeds), Mr. W. S. Woodburn (Glasgow). Treasurer: Mr. W. H. Woodruff. Librarian: Mr. H. Baldwin. Curator: Mr. Storer Bennett. Editor of Transactions: Mr. J. F. Colyer. Honorary Secretaries: Mr. J. H. Mummery (Foreign), Mr. C. F. Rilot (Council), Mr. A. Hopewell Smith (Society). Councillors: resident, Mr. E. Lloyd Williams, Mr. W. J. England, Mr. J. O. Butcher, Mr. J. H. Reinhardt, Mr. H. G. Read, Mr. H. Lloyd Williams, Mr. W. Rushton, Mr. R. Wynne Rouw, Mr. G. Northcroft; non-resident, Mr. Walter Harrison (Brighton), Mr. Alexander Kirby (Bedford), Mr. Martin Henry (Folkestone), Mr. D. Corbett, jun. (Dublin), Mr. Rees Price (Glasgow), Mr. G. O. Whittaker (Manchester), Mr. T. Mansell (Birkenhead), Mr. W. A. Rhodes (Cambridge), Mr. W. Glaisby (York).

BRISTOL EYE HOSPITAL.—On June 28th and two following days a very successful carnival was held at the Zoological Gardens, Clifton, in aid of the funds of the Bristol Eye Hospital. The carnival was opened by the Dowager Duchess of Beaufort and it is hoped that a considerable sum has been raised for the institution.

Reviews and Notices of Books.

Recollections of My Life. By Surgeon-General Sir JOSEPH FAYRER, Bart., K.C.S.I. London: William Blackwood and Sons. 1900. Price 21*s*.

THIS volume, which is most appropriately dedicated to Lady Fayrer in remembrance of 45 years spent together, is a brilliant record of experiences the equal of which have befallen few members of our profession. It contains the memories of a varied and eventful life, and from the way in which it is written we feel it must have given the author as much pleasure to put together as it does to the reader to peruse. The book will no doubt have a large circulation among the general public, and we can recommend it strongly to Sir Joseph Fayrer's civil brethren, who will thus have very clearly brought before them the great responsibilities attaching to the higher places in medical official life. By the medical officers of the army both at home and abroad the book will be read and treasured as the record of the life-work of a brother-officer who has been peculiarly successful in a higher sense than the one which usually appeals most strongly to human nature.

In some 500 pages Sir Joseph Fayrer has given us a record of the most notable incidents in which he has borne a part. The reader rises from his study of this book impressed with the thoroughness of Sir Joseph Fayrer's life-work, with the high ideal which he as a medical officer has ever sought to attain, with the feeling of how loyal he has been to the great profession of which he is proud to be a member, and how constant he has ever been in promoting the true dignity of the calling which he considers most noble. The story of his life is told in simple language and in a way which makes those who know the author almost feel that he is indeed speaking to them. In other words, the book is not merely a record of the man's doings, but also of the man himself—of his strong individuality.

The son and grandson of naval officers, Sir Joseph Fayrer in early days was attracted by the sea. His father, who retired from the navy with the rank of commander, was afterwards one of the pioneers of steam navigation and commanded the *Great Liverpool*, which was then the largest ocean-going steamer. At the age of 16 years young Fayrer was appointed a midshipman in the West Indian Mail Steam-packet Service and sailed under Captain Hart to the West Indies and South America, but in his nineteenth year, while at Bermuda during an epidemic of yellow fever, he became strongly impressed with the importance of the medical profession, seeing how highly it was valued and how great an influence its members exercised for good. In August, 1844, he started for England and became a pupil at the Charing-cross School of Medicine, where his chief friends were W. G. Hunter (now Sir William Guyer Hunter, M.D., K.C.M.G., Q.H.S.), subsequently Surgeon-General of the Bombay Army, and the late Professor Huxley. In July, 1847, having passed his examination at the Royal College of Surgeons of England, he was commissioned to H.M.S. *Victory* for service at Haslar Hospital, where one of his comrades was Andrew Clark, afterwards President of the Royal College of Physicians of London. In the month of October, 1847, having been allowed to resign his commission temporarily, he left England as physician to Lord Mount-Edgcumbe, and with him he travelled on the continent for a few years. While with the earl, in February, 1849, he received the degree of M.D. from the University of Rome, being the only graduate of the University who was not a Roman Catholic. It was at Rome that he had the good fortune to afford medical aid to one of Lady Malcolm's daughters, thereby securing the interest which subsequently obtained him his appointment

in India. Towards the end of the year 1849, through the interest of Lord Mount-Edgcumbe, he obtained a commission in the Ordnance Medical Department, then presided over by Sir John Webb, but after four months at Woolwich the service was reduced in numbers and then it was that, through the interest of Lady Malcolm, Sir R. Campbell, a Director of the Honourable East India Company, gave him an Indian appointment and he proceeded to Bengal as an assistant surgeon. On June 29th, 1850, he left Gravesend in the *Camperdown* for Calcutta, and he commenced his Indian service at Fort William on Oct. 9th, 1850. In April, 1852, he sailed for Rangoon as one of the medical officers forming the hospital staff of the Burmah Field Force and was present at the escalading of the Thilawa stockade. During the war he was literally field surgeon to the Burmese army. As a reward, in July, 1853, Lord Dalhousie wrote and offered him the Residency Surgeoncy at Lucknow, which he said he had reserved to bestow upon the assistant surgeon who rendered the most approved services during the war with Burmah. When he joined his appointment Colonel Sleeman was the Resident, and he duly instructed Fayrer in the ceremonial and etiquette which are deemed of such importance in a native court. His designation in his early days at Lucknow was "Residency Surgeon, Superintendent of the King's Hospital, and Postmaster"; he was also in charge of the Martiniere School and Superintendent of the Char Bagh, a large public garden. Sir William Sleeman was in due course succeeded by Outram, whose arrival was celebrated with great pomp. In September, 1854, Fayrer was appointed an honorary Assistant Resident, and thus had political combined with other duties.

It was at Lucknow, on Oct. 4th, 1855, that Fayrer married a daughter of Brigadier-General A. Spens, and it was about this time that Outram, charged with instructions from the Governor-General in Council, carried into effect the last important act of Lord Dalhousie's administration—the reorganisation of the Oudh Government, which necessitated the deposition of the King, and henceforward Oudh became a British province. Under the new *régime* Outram recommended that Fayrer should be made a Deputy Commissioner, but the Governor-General wrote to him suggesting that, as he had done so well in his profession, it would be a pity to give it up. In consequence he was appointed Civil Surgeon of Lucknow and Superintendent of Charitable Institutions. Part of his work at this time was to reorganise the postal arrangements and extend them over the whole province. Sir Joseph Fayrer relates many incidents connected with his professional life while at the court of Oudh—many of them are full of humour and all are well told.

There is much in this work which will please the sportsman, for Sir Joseph Fayrer relates tales of shooting expeditions in which all wild animals, from the lordly elephant to the humble snipe, formed a quarry. Many and varied also are his observations of animal and vegetable nature in the jungle and Terai, the contemplation of which evidently added a freshness and charm to his everyday life.

As Sir Joseph Fayrer is one of the survivors of the Lucknow garrison during the ever-memorable siege, the reader naturally turns to the story of those days and is not surprised to find that he has devoted more than 100 pages to the insurrection in Lucknow and Oudh and the siege of the Residency. Here every line is worth reading, for the descriptions are vivid and the excellent maps and plans enable the reader to follow with ease each detail and incident of those memorable days. Fayrer's work in those days as physician, hygienist, and soldier was indeed stupendous. He devotes but small space to the final act in the drama of the life of that great Anglo-Indian, Sir Henry Lawrence, for of this he has written elsewhere more fully, but he tells enough to enable his readers to follow the course of events on that saddest of the days which dawned for Lucknow's heroic defenders. The whole story of those days in Lucknow is both circumstantial and thrilling. Years after Sir Joseph Fayrer tells how he presented the aged survivors of his own garrison to the Prince of Wales, to whom also he pointed out the old positions and the ruins of his former home. Vivid also is the tale of the perilous march of the garrison to Cawnpore after the relief. His strong remarks on the subject of Havelock's deserved "V.C." are a vigorous testimony against the absurd regulations which at times prevent the decoration of brave men with the soldier's most coveted distinction.

In 1858 Fayrer returned to England and went to reside at Edinburgh with a view to take his M.D. degree. He relates that he was allowed a special examination just before returning to India to take up his appointment as Professor of Surgery in the Calcutta University. In the descriptions of his surgical work in Calcutta, of his labours as member of the Syndicate of the University and President of the Faculty of Medicine, as President of the Asiatic Society, and Trustee of the Indian Museum, and of his experimental work which led to the publication of his great work on the "Thanatophidia of India," there is much to interest and attract the reader.

Invested at an early age with the badge of the higher of the Indian Orders of Knighthood he rode with the Companions of the Order at the memorable Chapter when the Duke of Edinburgh was invested as a G.C.S.I. on the Calcutta maidan and at the Viceroy's request accompanied the Duke on his travels through the north-west of India—an opportunity which led to his appointment as physician-in-ordinary to His Royal Highness.

The year 1873 saw Fayrer appointed as a member of the Medical Board at the India Office under the presidency of Sir Ranald Martin, whom he afterwards succeeded, and brought him his election as a Fellow of the Royal College of Physicians of London, a circumstance which subsequently restricted his practice to that of a consulting physician, for etiquette henceforward forbade surgical work in which he had excelled in India and to which he was much attached.

About a hundred pages of the volume are devoted to incidents connected with the Prince of Wales's visit to India. The part that Fayrer played in that great and memorable journey through the Indian Empire is told with a becoming modesty, but leaves the reader impressed with the manner in which he prepared for his arduous and difficult duties and very sensible of the care with which he carried out the charge intrusted to him by the Queen. It was while at Dholpore in Rajputana that the Prince informed him that Her Majesty had telegraphed to the Viceroy saying that he was to be made a Knight Commander of the Star of India, and he afterwards received the accolade and the insignia from the Prince's hands at a Chapter held at Allahabad.

Of the later stages of his career in London and of the important work he carried out as President of the Medical Board and member of the Army Sanitary Committee the reader can obtain due knowledge. One of his most important acts was certainly the firm and consistent support which he gave during many years to the Army Medical School at Netley. Twice in bygone years was its existence threatened and twice was his strong hand put forth to stay the destroying mandate, Sir Joseph Fayrer going the length of privately addressing the Queen through Sir Henry Ponsonby and asking her to avert the danger. He also spoke strongly at a meeting of the Royal College of Physicians of London about the medical services and thereby helped forward the new warrants. On the many honours which have been accorded to Sir Joseph Fayrer by Her Majesty and by universities in this country and abroad we will not dwell; they

are, of course, noted in this volume which is the record of a long official life well spent.

Prefixed to the book is the best portrait of Sir Joseph Fayrer which we remember to have seen, his expression and attitude being faithfully reproduced. The illustrations of the book are excellent, among the most interesting being the pictures of his house at Lucknow before and after the siege. The binding and letter-press of the book add to it an additional charm.

Heart Disease in Childhood and Youth. By CHARLES W. CHAPMAN, M.D. Durh., M.R.C.P. Lond. With an introduction by Sir SAMUEL WILKS, Bart., M.D. Lond., F.R.S. London: The Medical Publishing Co., Limited. 1900. Pp. 98. Price 3*s.* 6*d.*

IN this small book Dr. Chapman has given a clear and interesting account of modern opinions with regard to heart disease in the young. He follows the views of Cheadle and Sturges as to the different clinical course, prognosis, and treatment of the disease in early life. He draws special attention to the frequency with which heart disease is overlooked in children owing to the ease with which compensation occurs and the consequent absence of symptoms, and quotes a number of clinical cases which bear this out. Dr. Chapman's directions with regard to the hygienic management of children who are suffering from heart disease is most sound and judicious. He protests against their being treated as having only a few years to live and strongly urges that where there is good compensation the boy should live an ordinary life, going to school and, under medical supervision, being allowed to take part in the less violent school games and sports. A large number of illustrative clinical records are given, as well as photographs and sphygmograms. Altogether the book forms an interesting and useful contribution to the literature on the diseases of early life.

A protest, however, must be entered against the practice of announcing books as accompanied by an "introduction" by some eminent man. The introduction by Sir Samuel Wilks in this book contains no information with regard to his own views but is merely a short testimonial.

The American Year-book of Medicine and Surgery. Under the general editorial charge of GEORGE M. GOULD, M.D. Medicine. London: Rebman, Limited. 1900. Pp. 656. Price 17*s.* (The two volumes, Medicine and Surgery, 30*s.*)

THE general scope of the American Year-book is so well known that no introductory remarks are needed from us. The excellent standard of the publication is well maintained in this volume and all the subjects are brought fully up to date. In a glance through the pages the reader is at once able to perceive the work which has recently been done by various observers in any particular disease. The plentiful but judicious use of bold type greatly adds to the use of the work for reference, and the wished-for information is soon found.

Dr. Alfred Stengel and Dr. D. L. Edsall (Philadelphia) are responsible for the section on "General Medicine." The article on Typhoid Fever is of great interest; we may especially note the remarks on Combined Typhoid and Malarial Infection, a subject which is now receiving a considerable amount of attention. Another sub-section well worthy of perusal is that on Congenital Lesions of the Throat.

The section on Pediatrics is edited by Dr. Louis Stair and Dr. Alfred Hand of Philadelphia. The subjects to which attention has been paid in greatest measure are those of hygiene, infant-feeding, and the disturbances of the digestive tract.

Dr. David Riesman of Philadelphia has put together the section on Pathology. He draws especial attention to Birch-Hirschfeld's valuable observations on primary pulmonary tuberculosis, enlarging on this writer's statement that "pulmonary tuberculosis in its first stage is, as a rule, a mucous membrane tuberculosis located in a medium-sized apical bronchus." The more recent discoveries in bacteriology are also duly chronicled and a large amount of attention is paid to toxins, antitoxins, and agglutination.

Dr. Archibald Church is the editor of the section on Nervous and Mental Diseases and gives a good summary of the work performed during the year 1899 in addition to the usual extracts collected from medical literature. Dr. Louis A. Duhring and Dr. Milton B. Hartzell of Philadelphia have collected the information on Cutaneous Diseases and Syphilis, while Dr. R. W. Wilcox of New York and Dr. A. A. Stevens of Philadelphia are responsible for the section on Materia Medica, Experimental Therapeutics, and Pharmacology. They remark that the trend of therapeutic investigation during last year was rather toward a working out of details and following out of theories prepared than in presenting new measures, and that praiseworthy attempts have been made in the direction of harmonising the results of laboratory work and bedside study. Dr. G. N. Stewart of Ohio has produced an interesting collection of the advances made in Physiology, while Dr. Wyatt Johnston of Montreal has collected some valuable statistics from writings on Legal Medicine. The section on Public Hygiene and Preventive Medicine is by Dr. S. W. Abbott of Boston, and the one on Physiologic Chemistry is by Dr. Walter Jones and Dr. Reid Hunt of Baltimore.

LIBRARY TABLE.

The Pasteurisation and Sterilisation of Milk. By ALBERT E. BELL, F.I.C., F.C.S. London: Rebman, Limited. Pp. 41. Price 1*s.* 6*d.*—This unpretentious little book is a reiteration of the well-worn arguments in favour of the pasteurisation and sterilisation of milk. Since milk is known to be a means of spreading disease there can be little doubt of the great advantages of a sterilised milk-supply, but as our only method adopted is that in which the milk is submitted to the action of heat it cannot be doubted that some important changes in the composition of the milk take place also in this process. The precise nature of these changes and their effect upon the dietetic value of milk are still wrapped in some mystery. The author describes several forms of apparatus both on a large and small scale which are well adapted for the sterilisation of milk and he details also the organisms which occur in milk and which give rise to disease. He might have extended his observations on the effect of sterilisation upon milk inasmuch as the subject has been somewhat widely discussed during the past year. One sentence which occurs on page 41 should have been a little more positive. It is stated that "it is therefore most probable that the milk sold in large towns which is a mixture of milk from numerous cows contains tubercle bacilli." Quite recently, it is added, the experiments and researches made by Dr. Obermüller established this fact beyond all doubt. If the author will refer to our columns he will find that the fact has been established again and again at times which can hardly be described as "quite recently." The book will be read by the lay reader with advantage since it points out the dangers arising from infected milk and the advantages of sterilised milk.

A Pocket-book for Chemists. By THOMAS BAYLEY, Assoc. R.C.Sc.I. Seventh edition, enlarged and revised. London: E. and F. N. Spon, Limited. 1900. Pp. 559. Price 5*s.*—We shall not be surprised if this book reaches many more editions than the present number, seeing that it is so useful. Indeed, to the chemical manufacturer, the metallurgist, the dyer, the distiller, the brewer, the sugar

refiner, the photographer, and the medical man in the quest of analytical data it is a *sine quâ non*. The present edition has been quite brought up to modern requirements. Although a pocket volume it contains an enormous number of data which must have entailed considerable work, while the task of editing and revising must have been no small one. We cordially congratulate the author not only on the excellent plan of arrangement but also upon the accuracy which characterises the pages of data and formulæ. This is no small compliment considering the great number of formulæ, figures, and mathematical data with which the pocket-book abounds. To the busy practical chemist the book is of greater value than a dictionary, for reference is easier and the subjects are limited to practical work.

A Text-book of Physiological Chemistry. By OLOF HAMMARSTEN. Authorised translation from the author's revised fourth German edition by JOHN A. MANDEL. Third edition. New York: John Wiley and Sons. London: Chapman and Hall. 1900. Pp. 628. Price 17*s*.—This work was reviewed in THE LANCET of March 18th, 1899, when the second edition was under consideration which was a translation of the third German edition and there are no essential changes either in plan or material in the present edition. But of course the subject has been brought completely into accord with the modern developments of science. The number of pages in the present edition, which is called "enlarged," is reduced by 80, which is due rather to altered paragraphing and arrangement of type than to the condensation of discussion. The translation is admirably done, and is clear and intelligible. The order in which the subjects are treated betokens also a systematic faculty. We still find no reference in the section on the Respiratory Processes to the elaborate work of the late (as we must now write) Dr. Marcet, F.R.S., although the work of German collaborateurs is freely cited. Hammarsten's original work has been frequently translated into other languages besides our own, of which several editions have appeared, a fact which is an indisputable argument in its favour as a book that is much sought after as an educational help. An admirable feature of the work is the copious references given in the foot-notes to original papers on some of the great physiological problems. The index, also, is very complete. The book may be recommended to the student commencing this subject, and besides, as a source of reference, to those who have completed their ordinary curriculum.

A Glossary of Botanic Terms. By BENJAMIN DAYDON JACKSON. London: Duckworth and Co. Philadelphia: J. B. Lippincott Company. 1900. Pp. 326. Price 6*s*.—Botanical science has accumulated such a vast number of technical terms, many of which are only occasionally met with, that a glossary of terms is really necessary to the right understanding of modern works on botany. The book under notice gives the derivation and accentuation of the words and in addition to the glossary contains an appendix giving a list of signs and abbreviations, a bibliography, and other supplementary matter. Bearing in mind the use of such a book it is a pity that a page of *errata* should have been necessary, and also that the list of additional words could not have been incorporated in the main list. These things will, no doubt, be put right in a second edition, but their existence in the first edition does not add to the convenience of the book, which, however, should prove of use in the reference library of any one interested in the science of botany.

Lehrbuch der Histologie und der Mikroskopischen Anatomie des Menschlichen Körpers. (Text-book of the Histology and Microscopical Anatomy of the Human Body.) Von Dr. Ladislaus Szymonowicz, ausserordentlichem Professor der Histologie und Embryologie an der Universität Lemberg. Lieferung III. Würzburg. 1900. London: Williams and Norgate. Preis M.3.—The third part of Dr. Szymonowicz's text-book includes about 60 pages of the text and 11 beautifully executed drawings in addition to some 50 figures scattered throughout the different pages of the work, in illustration of the thorough manner in which microscopical anatomy is taught at Lemberg. The parts of the body which are described and illustrated are the veins, the heart, the lymphatics, the thyroid, the suprarenal capsules and the coccygeal body. These are followed by a minute account of the digestive system from the mouth to the small intestine. The text is very clearly expressed, and the illustrations, mostly original, are most excellently drawn. We may at once say that Professor Szymonowicz's treatise will, when completed, be one of our most valuable works on human histology.

JOURNALS.

The *Veterinarian* for June exposes a singular dearth in its usual number of original clinical case notes. For this to be the case in a journal the strong point of which used always to be its clinical side makes it seem as if the veterinary practitioner was becoming very apathetic. It may be that, as the war in South Africa has removed a large number of rivals from England, he is too busy to jot down notes and write them up into clinical articles in his spare time. This month's number consists almost entirely of extracts from colonial or foreign sources. The first article is taken from the report of Mr. J. A. Gilruth, chief veterinary officer and bacteriologist to the New Zealand Government, and is headed "Tumour Formation in certain of the Domestic Animals." It is an interesting extract and is well illustrated. A summary of the same author's work on Actinomycosis, Parasitic Gastritis, Red-water, Milk Fever, Acute Congestion of the Kidneys, and other diseases of cattle and sheep is also given. A valuable editorial note summarises the recent work of Professor van Gehuchten and M. Nélis, wherein these writers assert that by a microscopical examination of one of the cerebro-spinal ganglia of a supected animal the diagnosis of rabies can be confirmed or refuted in a few hours instead of waiting until the result of inoculation becomes known. The annual report of the Principal of the Royal Veterinary College is concluded, this instalment including the Summary of the Researches made upon South African Horse Sickness and the Curability of Glanders. Mr. John Dollar contributes translations from Professor Cadiot's lectures on Clinical Cases and there is also an article on Tuberculosis Antitoxins by E. Merck of Darmstadt. Scientific extracts under the heading of the Month's Progress and reviews of books conclude the number.

The *Veterinary Journal* for June is even worse off than its contemporary the *Veterinarian* for clinical articles. The June number is almost entirely made up of reports of the proceedings of the various veterinary societies, the account of the quarterly meeting of the Council of the Royal College of Veterinary Surgeons, extracts from foreign or colonial sources, and reviews of books. Amongst the first-named are papers on Influenza, Anæsthetics, and Joint Evil. Dr. Bradford's paper on Rabies is concluded and a list of the successful candidates at the recent professional examinations in Edinburgh is given. As a great deal of this matter has already been published in the weekly organ of the profession it seems a pity that it should be utilised to fill up the monthly journals, particularly as the weekly paper is well known to have a wide circulation. More original work would be better appreciated.

TEIGNMOUTH HOSPITAL.—The fête which was recently held in aid of the funds of the Teignmouth Hospital resulted in the sum of £250 being raised for the institution.

THE LANCET.

LONDON: SATURDAY, JULY 7, 1900.

MR. BURDETT-COUTTS'S letter to the *Times* of June 27th was terrible reading. No wonder it stirred the feelings of the British people and caused the most anxious inquiries to be made in every direction at all calculated to elicit information on the subject—and no wonder also that much of the correspondence which ensued in the press owed its inspiration to the heart rather than to the head. Despite all that human foresight and ingenuity can devise wounds and privation are inseparable from war. Some writers seem to have forgotten this. The real terror of Mr. BURDETT-COUTTS'S letter lay not in his statement that horrors had occurred but in his deliberate allegation that they had occurred from causes which might have been foreseen and which were wholly preventable. The case is one of national concern, one which touches the national sense of honour and humanity, and should be kept altogether above any mere party interest. However painful the subject may be, heated and impassioned discussion is quite out of place on such an occasion. The aim and object of everybody should be to elicit the truth, and the whole truth, in a spirit of independence, and in that spirit we propose to discuss the subject to the best of our ability. It goes without saying that everything which affects the honour and reputation of the medical profession deeply concerns us, and we fearlessly accept the position that the medical service in South Africa is to be held accountable for the trust committed to it. If it can be shown that it was within the power of the medical service to have prevented the terrible scenes described by Mr. BURDETT-COUTTS, or if the things which he alleges to have happened appear on investigation to be attributable to any culpable neglect on its part, then a well-deserved obloquy and punishment should fall upon the culprits. On the other hand, unless war is to be rendered impossible it is surely conceivable that exceptional conditions arising out of the circumstances of a campaign may occur which are practically beyond human control, or which at any rate in the judgment of those in supreme command are of so imperative a nature as to render the vicarious suffering and sacrifice of some unavoidable in order to secure the safety of the remainder or the achievement of strategical success. Decision in such momentous situations falls, and rightly falls, within the province of the Commander-in-Chief and that of his staff. The duty of the medical authorities is to represent the facts and to advise as to what should be done; there their official responsibility ends.

The picture presented to us by Mr. BURDETT-COUTTS of the almost indescribably bad condition of the sufferers from typhoid fever closely packed together in bell tents and marquees—and we purposely select this as the most graphic, tangible, precise and striking instance of alleged neglect—was such as to lead the least sensitive to exclaim: Are the facts correctly stated, and, if so, were these horrors unavoidable under the circumstances and exceptional, or were they more or less typical of the general condition of the medical arrangements? Again, if these things were unavoidable how long did such a state continue and was it remedied with the least practicable delay or not? Such were the questions we asked ourselves at the moment, accepting Mr. BURDETT-COUTTS'S statements as substantially true in the meantime. If neglect can be proved the offenders must be punished. But the fullest inquiry should precede punishment and the military exigencies must not be lost sight of. We rose from a perusal of the debate in the House of Commons with a well-grounded feeling of assurance that the Army Medical Service will turn out after an honest and unbiased investigation to have been both powerless and blameless in this matter. We confine ourselves to the occurrences at Bloemfontein and Kroonstadt, putting aside for the present all other allegations emanating from any places elsewhere. And it seems to us quite irrelevant to the subject to inquire whether there was any want of physicians and nurses, because where the most elementary necessaries for the accommodation, feeding, and treatment of the sick were absent no amount of physicians and nurses could, practically speaking, have been of any avail. Again, while we thoroughly accept as indisputably true all that Sir WILLIAM MAC CORMAC, Mr. TREVES, and others have said about the condition of the hospitals, we may put much of their evidence aside as irrelevant to the present issue, because the results of their personal inspections were only applicable to the times and places at which they were made. We are quite content to accept, for the sake of argument, Mr. BURDETT-COUTTS'S description of what he saw. We only ask that judgment on the whole question may be suspended until more is known.

No fair-minded or reasonable person can hesitate, after reading Mr. WYNDHAM'S speech, to arrive at the conclusion that the provisions made in this country for the hospitals of the army in South Africa were most carefully considered, while the transit of all supplies to the Cape was thoroughly well arranged. We see no reason for altering the opinion which we expressed months ago that everything had been provided for the medical service on a more liberal scale than had ever been attempted before. It is a ridiculous assumption that the medical authorities of the War Office were not thoroughly alive to the fact that there would be a large amount of enteric fever. The experience of every modern campaign on record furnished the information. They could not, of course, foresee the occurrence of the sieges at Ladysmith and elsewhere, or the capture of the waterworks by the Boers at Bloemfontein for example; nor could anyone have foretold the incidence of disease in the form of big outbreaks at any given time or place; but the War Office took care to provide for the occurrence of a large aggregate amount of enteric fever. We can only suppose that Sir WALTER FOSTER'S speech in the House of Commons with reference to the sending out of a small sanitary commission was prompted by political motives, for the efforts of such a commission would, it seems to us, have been completely useless unless the commissioners

had explored, say, Kroonstadt and Bloemfontein some weeks before Lord ROBERTS's arrival. Would not the commissioners have been impeded in their work by the Boers? Such a commission would have been valueless, and its proposal shows that Sir WALTER FOSTER did not know where to look for a clue to the difficulty. Transport is *the* difficulty in every war and it has been pre-eminently so in this one. At the beginning of the campaign the British forces were not only outnumbered, but their plans were frustrated by the mobility of their foes. When Lord ROBERTS assumed command he had a larger and much more mobile force at his back. A number of very rapid and sweeping marches were made, by which the army altogether outmarched its supplies and had to depend upon a single and precarious line of rail. This was frequently interrupted, while his convoys were also captured and his stores raided by the enemy. Lord ROBERTS either might not have gone to Bloemfontein and Pretoria at all or might have doubled the carrying capacity of his railway before doing so. We cannot suppose that either alternative would have been deemed by anyone a satisfactory proceeding on his part. Still, the matter rested with him and with his chief of the staff, who was supposed to have the army transport under his special charge. Whether Mr. BURDETT-COUTTS was right or wrong in his contention that if the railway trucks had been properly utilised all would have been well is a matter which he must settle with the military authorities. Lord KITCHENER is probably the only officer in a position to give full and complete information on the point. It is clear, however, from the extracts which Mr. WYNDHAM read from the diary of the Principal Medical Officer at Cape Town that Surgeon-General W. D. WILSON was thoroughly alive to the importance of getting his general hospitals to Bloemfontein, but was unable to do so on account of the great pressure of traffic.

Mr. BURDETT-COUTTS will pardon us for remarking that he is not the sole and exclusive possessor of feelings of humanity or the only person animated with a keen sense of responsibility in regard to the requirements of the sick. Let it be clearly understood that we fully credit him with having been shocked and distressed by what he saw and with having been actuated by a conscientious sense of duty in the course he has taken; and we most sincerely hope that it will have the effect of leading to the fullest inquiry and be productive of the greatest benefit to the sick and wounded soldier. But we do find fault with him in that he did not, whilst on the spot and enjoying peculiar advantages in the matter of introductions, make a representation to Lord ROBERTS or apply for advice and information to the Central Red Cross Society which has large funds at its disposal and agents and depôts at the seat of war. He should have done either or both of these things before having recourse to the publication of his letter.

WE have recently[1] published a communication by Dr. PAVY on Differentiation in Diabetes. It has long been recognised by physicians that one of the most striking features belonging to diabetes is its varied manifestations in different cases; also that correct prognosis and treatment mainly depend upon an accurate knowledge of the phenomena, clinical and chemical, by which the forms met with in actual practice are characterised. In Dr. PAVY'S article two classes of cases are most ably differentiated, and a study of his remarks will enable practitioners more fully to understand the principles upon which cases of diabetes may be treated and the facts upon which a prognosis may be founded.

As is well known there is a class of case in which the eliminated sugar is solely derived from the food. It constitutes what has been appropriately named the "alimentary" form of diabetes. Dr. PAVY'S observations are chiefly from a practical point of view and therefore he does not enter into a theoretical discussion. He states that in this variety of the disease the carbohydrate matter of the food fails to be dealt with in the system in such a way as to be placed in a proper position for utilisation. As a consequence it becomes discoverable as sugar in the circulation and is thence discharged as waste material with the urine. It is important to remember that in this "alimentary" form of diabetes the abnormal state observed in connexion with the urine consists purely and simply of the presence of dextrose. As a result when the urine is examined quantitatively by cupric oxide reduction and the polarimeter the figures given by the two methods stand in accord or sufficiently so for the difference noted to fall within the limits of error of observation. As a further point in connexion with this kind of urine it is found that when the dextrose has been removed by fermentation with yeast and Fehling's solution no longer gives any reaction the polarimeter also fails to afford any evidence of either right-handed or left-handed optical activity. Simply placing the urine aside in a warm situation for 24 hours with some broken-up German yeast ordinarily suffices for the complete removal of the dextrose. One other point has to be taken note of for a full understanding of the chemical phenomena in connexion with urine in diabetes—namely, that the urine belonging to the "alimentary" form of the disease does not possess the abnormality which leads to the production of a coloured reaction with ferric chloride. Turning now to the second class of case which Dr. PAVY describes we find that the dextrose in the urine, instead of being derived solely from the carbohydrate matter of the food, is also present as a consequence of abnormal proteid disintegration. This is a much more serious matter. By faulty metabolism a tissue breaking-down occurs, attended with the production of sugar associated with other abnormal degradation products. Through this proteid disintegration consequences arise which do not follow on the simple faulty assimilation of carbohydrate matter. Dr. PAVY points out that pernicious results may ensue from the sugar that reaches the system from mal-assimilated carbohydrate matter, but further and graver effects arise from the condition attended with the production of sugar from faulty degradation metabolism. It is to the presence of one or more of these products of disintegration accompanying the sugar that diabetic coma is attributable. Thus a form of danger is engendered which does not attend the abnormal existence of the sugar alone. The term "grave" has usually been adopted in defining this class of case.

[1] THE LANCET, June 16th, 1900, p. 1706, et seq.

After reading Dr. PAVY'S description, however, we agree with him that the conception to which that term gives rise does not felicitously fit in with what is desirable for general use. The term he proposes—"composite"—more accurately meets the circumstances in relation to the existing condition and also stands more appropriately in contrast with the "alimentary" or simple form of the complaint. We think, therefore, that the expression "composite" should be accepted to distinguish that form of diabetes in which evidence is presented of tissue disintegration constituting a partial source of the dextrose eliminated from that in which the dextrose is derived solely from the food. In brief the "composite" form of the disease is characterised by the presence in the urine of sugar, together with the products of faulty tissue breaking-down. Dr. PAVY then goes on to explain what are the series of abnormal products discoverable in the urine in the "composite" form of diabetes. The chain in its successive stages of descent runs as follows: β-oxybutyric acid, diacetic acid, and acetone. It is known that traces of acetone may be met with in normal urine, but the presence of the other principles is usually regarded as pathological. They are indicative of abnormal proteid destruction and their amount may be taken as furnishing a measure of the extent of its occurrence. This is of course an important point, as we are thus enabled to read off in a given case the magnitude of the morbid action in play in the direction in question. Dr. PAVY proceeds to show the manner in which the estimation can be effected by methods adapted for clinical application. We do not propose to dwell in detail on these measures, but we may mention it is the levo-rotatory β-oxybutyric acid that is found and consequently this action takes away from the dextro-rotatory effect produced by dextrose, and thus the results given by estimation with cupric oxide reduction and the polarimeter are not in accord as they are with the "alimentary" form of diabetes; in the "composite" variety a reading is given it may be much below that which would have resulted if the dextrose had stood alone, and consequently correspondingly below the figures given by cupric oxide reduction. By the difference in the result noticed between this test and that afforded by the polarimeter an indication is given of the extent to which abnormal proteid disintegration is occurring. Supplementary information is obtainable by fermenting the dextrose away and then examining with the polarimeter. The optical activity of the oxybutyric acid is then allowed to come into unopposed play and a left-handed rotatory effect is shown, standing proportionate to the amount that is present. Finally, the presence of diacetic acid may be demonstrated by the ferric chloride test.

We have not space to comment further on Dr. PAVY'S interesting and instructive article. We have laid especial stress upon the chemical phenomena of the urine because they are less understood and appreciated than the clinical manifestations of the disease, but are equally important in the treatment. It is true that the examination has to be made by an expert, but at the present time no difficulty need be experienced in having the required analysis carried out at the numerous laboratories established for the purpose. It is obvious from what we have said above that it is of supreme importance that the practitioner should be able to decide as to which variety of the disease he has to deal with in any particular case. If it should prove to be of the "alimentary" form the treatment is simple and the prognosis favourable; should it prove, however, to be of the "composite" form the treatment is more complicated and severe whilst the prognosis is much less favourable. In a recent leading article[2] we drew attention to a paper published in our columns by Dr. SAUNDBY, and Dr. PAVY'S remarks are closely in accord with his. We need not, therefore, dwell again on the subject. We feel, however, that these two writers by their recent communications deserve the thanks of practitioners for bringing before their notice the most modern views as regards the prognosis and treatment of a disease so prevalent as diabetes.

THE Bill to amend the Companies Act, the second reading of which was carried through the House of Commons on June 26th, contains two clauses which, as the Minister in charge of the Bill remarked, are not germane to it. This is doubtless a truism, but whether the clauses be germane or not they are of the utmost importance to the medical profession. The object of the new Bill is, we take it, to render impossible for the future such instances of fraudulent trading under the guise of a company as have of late years shocked the public mind. Parliamentary Bills as a rule say what shall be done and not what shall not be done, and until lately it would have been considered as likely that medical practice should be carried on by a company as that the revision of the Nautical Almanac should be dealt with in the same manner. But the idea has been seriously acted on and various recent instances have occurred of companies, with more or less medical names implying medical function and practice and composed of persons with no real medical qualifications, pretending to practise medicine and to perform duties only legally to be done by practitioners on the Medical Register. Therefore, although the clauses dealing with medical and dental practice by companies may not be strictly germane, yet we contend that in a Bill such as the present the subject may very well be dealt with.

Nothing can be more clear from the various Acts and Charters regulating medical practice than that the Legislature intends that qualification to practise medicine in any or all of its branches is to be a personal matter. It is to apply to individuals and not to companies. There is something especially unsatisfactory in the idea of companies undertaking to carry on the profession and practice of medicine, and it has been recognised on all hands that such practices should be rendered impossible. The only question was as to the best way in which to stop this abuse—whether by a separate Bill of one clause, as in the Bill of the Lord Chancellor last year, or by a clause in the Companies Bill as recommended by a strong committee of the House of Lords. Happily, the latter course has been pursued by the Government, and in the Companies Bill of this session, with the names of Mr. RITCHIE and the Attorney-General

[2] THE LANCET, June 2nd, 1900, p. 1596.

and the Solicitor-General on the back of it, and ordered to be printed on Feb. 12th, we find the following section:—

3. It shall be unlawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife, and if any company contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding *five pounds* for every day during which the contravention happens.

We hope to see the Bill with this section included safely through Parliament during the present session. It is true that the medical profession, which is well informed as to the dangerous and audacious attempts by companies to practise medicine, was a little shocked when the President of the Board of Trade on the second reading of the Bill in the House on June 26th suggested, as we have already mentioned, that this section and another with reference to pharmacy might be left out of this Bill as being, though good in themselves, not really germane to it. This was a most disappointing line for Mr. RITCHIE to take at this advanced period of the session in regard to so admirable a part of his own Bill. We cannot doubt that he will reconsider this position and abandon it. He will admit that the chances of getting any such clause through as a separate measure at this late period of the session and after the passing of a Bill dealing generally with the abuses of the Companies Acts will be very slight. Fortunately we have his own authority for approving the principle of Section 3. He is the chief sponsor for the Bill, and in the debate on the second reading he admitted frankly that the amendment of the law which the section provides would be a beneficial alteration. His real object must be to make "companies" respected and to restrict their undertakings within limits that will make them safe and beneficial to the public. We do not gather that he has any strong objection to the clause remaining in the Bill. He said that the Standing Committee to which it has been referred must decide whether it should be proceeded with or struck out and relegated to some other Bill at some other time, but we are glad to learn as we write that the Committee has voted in favour of retaining the section. It would be a mere academic waste of time for the Government after this action of the Committee to argue further for leaving out the clause, the more so as, if we are rightly informed, Mr. RITCHIE has promised its promoters to urge the Lord Chancellor to re-introduce it as a separate measure if it be dropped out of the Bill. Mr. RITCHIE has already left this question practically to the Committee, and though its decision is against him it is only formally so. The decision is against him only in the sense of method and time and not in that of principle. It will gratify not only the General Medical Council and the medical profession, but all who have the reputation of companies at heart, to know that the principle involved in Section 3 has the approval of Mr. RITCHIE and the legal members of the Government and has found a place in the Companies Bill, which is likely to be one of the few measures of a memorable session dealing with domestic and peaceful questions. We venture to hope that he will cheerfully accept the vote of the Committee and give Section 3 the same Government help which he gives to the other portions of the Bill.

Annotations.

"Ne quid nimis."

THE NEW UNIVERSITY OF LONDON.

THE statutes and regulations made for the new University of London by the Commissioners appointed under the University of London Act of 1898 were passed in the House of Commons without opposition on Friday, June 29th. On July 2nd the foundation-stone of a new hall for the teaching of Economics and Political Science, which is a new faculty included in the University by the Commissioners, was laid by the Bishop of London in Clare Market almost on the line of the projected street from Holborn to the Strand. The site has been given by the London County Council, who will also contribute £2500 a year towards the expense of carrying on the work of the school, while Mr. Passmore Edwards has vested the sum of £10,000 in three trustees for the erection of the building. A new start has thus early been made for the future education of the metropolis. We presume that the different bodies interested will soon begin to elect a Senate and that the constitution of the three standing committees—viz., the Academic Council, the Council for External Students, and the Board to Promote the Extension of University Teaching, will at once follow. The members of Convocation and the teachers of the University in its eight faculties of Theology, Arts, Laws, Music, Medicine, Science, Engineering, and Economics and Political Science, are qualified as members of the University by the fact that the statutes are now in force. It is most important to the medical students of London that the Senate of the new University should quickly come into existence, in order that arrangements may be made with the Royal College of Physicians of London and the Royal College of Surgeons of England, or either of them, to conduct jointly with the Senate examinations in such portions of the subjects included in the course of study for a medical degree as may be agreed upon. It is now 12 years since Lord Selborne's Commission was appointed for the hearing of the evidence for and against the formation of a Teaching University in London and to report thereon. The granting of medical degrees by the two Royal Colleges had been discussed by a joint committee and the movement for promoting a Teaching University had been thoroughly considered for some years before the appointment of the Royal Commission. We are naturally anxious that organisation of the new University should not be unduly delayed, for the medical profession has long waited for reform.

THE "LIGHT TREATMENT."

MR. MALCOLM MORRIS has had under treatment by the Finsen electric-light method for more than two months several exceptionally severe cases of lupus vulgaris, and on Saturday afternoon last, June 30th, was able to give a very successful demonstration of the method to a number of medical men interested in the new departure. The premises which Mr. Morris has secured for the purpose of carrying out the "light treatment" are situated at 1A, Berkeley-gardens, Campden-hill, and are fitted up with every requisite for applying the new method. The particular apparatus used at 1A, Berkeley-gardens was procured by Mr. Morris from Copenhagen and has been in this country for nearly two years, but circumstances have prevented the apparatus being put into systematic use until some months ago. The apparatus required for the treatment by means of artificial light consists of three portions. First, a powerful electric

arc lamp is needed of from 55 to 75 ampères current; secondly, means must be provided for cooling the light; and, thirdly, it is essential that the operators should be able readily to concentrate the light in a suitable manner. The electric arc lamp is employed because it is found that its light is not only rich in chemical rays but is also less endowed with heat rays than ordinary sunlight. Further, in this country it is not possible to depend on a regular supply of sunlight which may, however, when available, be substituted for electric light with some necessary variation in the apparatus. For purposes of treatment the light is too hot and it is therefore passed through a form of telescope fitted with lenses of crystal and with distilled water for the purpose of absorbing the heat rays. Jackets of cold water are also so arranged that any chance of complications from the action of heat is avoided. Inasmuch as only a small portion of the diseased surface can be treated at one sitting provision is made for concentrating the light on a small spot a little larger than a florin. To those watching this process carried out it seemed that the attendants manipulated a patient with a view rather of bringing the part to be treated into focus than of focussing the light itself on to the desired place. Though naturally pleased with the favourable course taken in the cases of lupus vulgaris submitted to this treatment Mr. Morris very clearly pointed out to those present that the whole subject must be considered in a tentative way only and they must not allow themselves to make exaggerated statements about curing lupus, though of course the procedure was very satisfactory in many ways. It could be fairly said from the cases demonstrated by Mr. Morris that the method was painless, that no anæsthetic was required, and that there was nothing in it to frighten or repel a patient. Put very briefly a medical man could safely assert that given a powerful electric arc light, with suitable telescopes fixed at the right distance so as to concentrate the light properly cooled on to the patient's skin as he lies on a couch (if the situation of the lupus was convenient for focussing), the results would be in a large proportion of cases exceedingly satisfactory. The drawbacks are that the treatment is a tedious operation, the patient requiring very long and frequent exposure to the light, and that the longer the treatment the less power the light has of piercing the tissues in any particular case. In fact, there seem to be three factors specially detrimental to the success of this method: scar tissue, blood, and pigmentation. Mr. Morris does not appear to accept the theory that the chemical rays act in a remedial manner entirely by their bactericidal power, but space does not permit of discussing this point. The curative agency of these chemical rays does not seem to be confined to lupus vulgaris, for Mr. Morris showed a case of lupus erythematosus in which great improvement had resulted, and he also exhibited a typical case of rodent ulcer in which the hardness had disappeared, leaving only a superficial healing ulcer. The success of the demonstration was added to by some interesting remarks from Dr. A. Barry Blacker and Dr. F. Harrison Low. Mr. Morris was helped by Mr. S. E. Dore, his clinical assistant at St. Mary's Hospital, in carrying out the method of treatment.

SEPTIC SORE-THROAT AND INFECTED MILK.

DR. J. KING WARRY, medical officer of health of Hackney, has forwarded to us a copy of a report which he laid before the Health Committee on June 7th. The report deals with an outbreak of sore-throat which occurred in his district in April and also during a part of May. The disease was of a septic character and appeared to be connected with one particular milk-supply which in the report is designated as X. An analysis of 10 cases showed that in every case there was tonsillitis. In two cases there was also superficial ulceration. In every case there was cervical adenitis and in one case this went on to suppuration. The temperature was raised and the rise persisted for as long as a fortnight after the tonsillitis had disappeared. The temperature was of an intermittent type with profuse sweating. In one case acute septicæmia with fatal pneumonia supervened. In two cases acute nephritis with hæmaturia came on about a week after the commencement of the attack. In one case purpura hæmorrhagica occurred. Dr. Warry sent out a circular to every medical man in the district asking whether he had met with such cases as those of which the symptoms are detailed above and if so whether the milk-supply to the affected patients was from a common source. A bacteriological examination of suspected samples was carried out at the Jenner Institute, but no light was thrown on the matter. The circular resulted in providing details of 151 cases occurring in 88 households, all, with very few exceptions, being in Upper Clapton and Stamford Hill. Of these 138 cases occurred in 75 households, all of which were supplied with milk by X. Dr. Warry inquired of X from whom he got his milk, but X declined to say, being within his legal rights in so doing. "In some way," concludes Dr. Warry, "the milk supplied by X was the cause of the septic sore-throat disease."

THE EAST SUFFOLK HOSPITAL.

AT the anniversary Court of Governors of the East Suffolk Hospital, which was held on June 27th, a most important resolution was passed by the narrow majority of one which in future may have very serious results for the honorary medical staff. Hitherto the honorary medical staff have been elected for life and the elective body has consisted of the governors, or rather of some 400 members of the general body of governors. By the new rule members of the medical staff were to be elected for only ten years with the option of re-election at the end of the first ten years for a like period, and in addition the election was to be taken out of the hands of the 400 governors and transferred to the members of the board of management, who number 80. The motion was put by the Rev. T. M. Morris, who said that he spoke as the representative of the late board of management. Dr. W. A. Elliston, in opposing the proposed alteration, said that if carried it would cause a great deal of friction. Besides this the proposal did not come from the whole 80 members of the board of management, but only from the 12 members of it who were elected annually as a weekly board. The proposed new rule would simply put the medical staff in the position of being practically servants to the board of management. Personally he thought that there should be an age-limit, and for his own part he should be quite ready to retire at the usual retiring age—namely, 60 years. The proposal to disfranchise the governors in favour of the board of management simply meant the curtailing of the privileges of the governors and that would be disastrous for the funds of the hospital. The medical staff had quite made up their minds on the matter. Dr. R. K. Casley, in endorsing Dr. Elliston's views, said that a medical man's judgment was better at the end of ten years than when first elected. Some people thought that a change of clergyman at the end of ten years, or even of three years, was desirable. A hospital existed for the benefit of the patients and not as a dumping-ground for various young medical men. Eventually the proposal was carried by 19 votes to 18. The chairman then put to the meeting certain alterations which the rule just carried entailed, among others one which would make the whole of the medical staff members of the elective body, but eventually the matter was left over to be decided at a future meeting of governors. It must be remembered that the essence of a hospital consists of three things—money, patients, and

medical men. The last two are interdependent, and without either a hospital is non-existent. But although a hospital cannot get on without funds and subscribers it probably could get on without a lay board of management, and this is a fact which many boards of management seem to forget.

THE POSITION AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

AS a result of the statement which has been issued to the governors by the medical and surgical staff of the National Hospital for the Paralysed and Epileptic we understand that a full inquiry will be instituted without delay. We have received a letter from the medical committee conveying their desire to settle the questions at ssue between themselves and the board of management without appeal to the public. Under these circumstances we refrain from publishing either the statements of the staff or the rejoinder made by the board, and content ourselves at this juncture with saying that we trust that under no circumstances will the staff forego their just demand for representation on the governing body of the institution which owes its public utility to their efforts.

THE THIRTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE programme of fêtes which we published in our issue of June 23rd, p. 1821, has been slightly modified owing to the wish expressed by the President of the French Republic that he should close the Congress. The programme will therefore now run as follows. On August 2nd Dr. Lannelongue, the President of the Council, will give an evening fête in the name of the Government of the Republic. On August 3rd members of the Congress will be invited to an evening fête by the President of the Congress. On August 5th the fête given by the Bureau and Organising Committee of the Congress will be held in the Palais du Senat and the gardens of the Luxemburg. On August 7th the municipal council will hold its fête in the Hôtel de Ville. And, finally, on August 9th the President of the Republic will give his reception in the Elysée.

EXEMPTION OF PARALYSED LIMBS FROM THE SYPHILITIC EXANTHEM.

AT the meeting of the Société Médicale des Hôpitaux of Paris on June 15th M. Danlos related the following case. A man, aged 23 years, contracted syphilis. Six weeks after the appearance of the chancre a papular eruption appeared on the trunk, which took about three weeks to become generalised. Then the patient entered hospital with a confluent papulo-acneiform eruption which was very abundant on the trunk and less marked on the arms and left leg. The face was only slightly affected. The right lower limb was completely free from the eruption. On the right buttock and right side of the abdomen the lesions were numerous, but below the groin and the gluteo-femoral fold there was not one. In infancy the patient had suffered from infantile paralysis and the development of the right lower limb had been greatly checked. It was eight centimetres less in length than the left. The knee was semi-flexed and the foot was in a condition of equino-varus. All the tissues of the limb were decidedly atrophied except the skin which appeared to be normal. The temperature was lower on the right than on the left side. When the surrounding temperature fell the limb readily became purple. In spite of this it was, according to the patient, always moist. When the patient stood for a short time it became manifestly redder than the sound limb. The immunity from the eruption evidently depended on the atrophic condition of the limb. Similar cases have been recorded. In 1896 M. Jolly brought an almost exactly similar case before the society. Dr. Boulogne published a case in his *Thèse de Lille*, 1897, which differed in the fact that the paralysis was infantile spasmodic hemiplegia, and another in which the eruption was not the syphilitic exanthem but tuberculo-ulcerative syphilides, lesions which, however, are usually localised. Immunity of paralysed limbs to specific eruptions is not constant. M. Danlos observed in a man, aged 61 years, the subject of old hemiplegia, that the secondary syphilitic eruption was a little more abundant on the paralysed side. In the discussion which followed M. Merklen referred to a case of small-pox in a child the subject of infantile paralysis in which the pustules did not develop on the atrophied limb, and also to a case of psoriasis in which a limb, atrophied from infantile paralysis was exempt from the eruption. As to the explanation of such cases, nervous influence, alteration in the structure of the skin, defective circulation, and lowering of temperature may all be invoked, but definite proof as to the cause is wanting.

POST-GRADUATE CLINICAL STUDY IN THE METROPOLIS.

THE endeavour of the metropolitan schools of medicine to supply some sort of post-graduate teaching in London has proved far more successful than was at first anticipated. It was felt that the patients had already reached the limit of their endurance in the way of examination and the teachers the limit of their endurance in the way of teaching; for this reason it was decided to admit qualified medical men to the ordinary clinical instruction and clinical advantages of the medical schools, rather than to organise an independent post-graduate course. In this way it has been possible to throw open the best clinical material of the metropolis by issuing tickets at an almost nominal fee conferring the right to attend the practice of all departments of nine of the large metropolitan hospitals. Not a few of those who have come for a flying visit from Canada and the United States, after testing the scheme for a period of three months or more, have thought it worth while to stay a year or so as ordinary students to obtain the diploma of the Conjoint Board. Detailed information and prospectus may be obtained from the honorary secretary, West Wing, Examination Hall, Victoria-embankment, W.C., by letter or by interview between the hours of 12.30 P.M. and 3 P.M. daily, excepting Saturdays.

THE PLAGUE IN SAN FRANCISCO.

SOME two months ago rumours were current that plague had broken out in the Chinese quarter of San Francisco and reports which from time to time came to hand from that city, although vague, conveyed the impression that the true situation was being concealed and that the disease prevailed much more extensively than was generally supposed. Owing to this belief a feeling of dread sprung up throughout the United States that the plague had indeed gained a foothold in San Francisco and the fear was freely expressed that unless the most stringent measures were taken the pestilence, as in Australia, might be disseminated along the Pacific coast. In order to ascertain the exact position of affairs and to relieve the minds of the American public the *New York Herald* induced Dr. George F. Shrady of New York to proceed to San Francisco to make a careful inquiry into the matter. Dr. Shrady, after a stay of a week in San Francisco, during which time he visited every section of Chinatown under the escort of the police and health authorities, and after assisting in a necropsy on the body of a Chinaman suspected of dying from plague, came to the conclusion that, while there could be no doubt that the malady was, and had been, present in a

sporadic form, the scare was absolutely unwarranted, and that to all intents and purposes all fear of a widespread epidemic was ridiculous and unfounded. With regard to the condition of Chinatown and the duty of the San Francisco health authorities Dr. Shrady has this to say: "It matters not what money it may cost or what labour may be involved, the Board of Health of San Francisco has upon its shoulders a solemn duty which it must perform. The excitement created by the plague has called to the attention of the authorities the outrageously unhealthy state of Chinatown. Neither the people of San Francisco nor the authorities who represent them can afford to wait. Chinatown is known throughout the world as one of the filthiest quarters in existence, and San Francisco will not be relieved from the suspicion of other cities and States until it has removed this plague spot." It would therefore appear that the alarm caused by the occurrence of plague in San Francisco will really prove to be a blessing in disguise. Unsavoury Chinatown will doubtless be thoroughly cleansed and a district which has always been a menace to the whole city will be placed in a proper sanitary condition.

BARKER ANATOMICAL PRIZE.

STUDENTS who are expert dissectors will be interested in the announcement that the Barker Anatomical Prize of £21 is offered for competition and is open to any student whose name is on the anatomical class-list of any school in the United Kingdom. The subject appointed is a dissection of the fifth nerve, especially with reference to the Gasserian ganglion. The preparations must be sent to the Curator of the Museum, Royal College of Surgeons in Ireland, Dublin, before March 31st, 1901, each being marked with a fictitious signature and accompanied by a sealed envelope bearing outside the same signature and containing the competitor's name, together with a declaration that the work has been carried out by himself. The printed form necessary for the declaration can be obtained from the Curator. The cost and risks of transport must be borne by the student.

THE CLOSING OF PUBLIC ELEMENTARY SCHOOLS.

THE procedure to be adopted in order to enforce the closing of public elementary schools is so simple and can so speedily be brought into action that it is surprising to find not only members but even clerks of School Boards who appear to be quite unacquainted with the precise requirements of the Education Code. An instance in point reaches us from a district in South Wales where measles is now epidemic. The head-master of the Board school found his attendance had fallen from 97 pupils to 17 and he appeared before the School Board armed with an "order" from the local medical man to close the school. The Board was about to pass a motion to close when their clerk stated that such a motion was quite unnecessary but an "order" must be obtained from the medical officer of health of the district, whereupon the head-master and the clerk were deputed to wait upon this official who without demur gave the required document. Article 88 of the Education Code reads:—

"The managers must at once comply with any notice of the sanitary authority of the district in which the school is situated, or any two members thereof, acting on the advice of the medical officer of health, requiring them for a specified time, with a view to preventing the spread of disease, or any danger to health likely to arise from the condition of the school, either to close the school or to exclude any scholars from attendance; but after complying they may appeal to the department if they consider the notice to be unreasonable."

It will be observed that the proceedings may be likened to a safe with two keys, both of which are required to open its door. One key is in the possession of the medical officer of health and the other in that of the district council or any two of its members. Either is powerless to act alone, but with joint action a school or a department of a school may be closed at a few hours' notice. The medical officer of health may advise the closing, but can go no further; he certainly cannot issue an "order" to close. The district council or any two of its members can require a school to be closed, but only "acting on the advice of the medical officer of health."

TENDENCY TO HÆMORRHAGES IN EXOPHTHALMIC GOITRE.

IN a recent number of the *Neurologisches Centralblatt* (April 15th) Dr. J. Popoff reports two fresh cases of exophthalmic goitre with pronounced tendencies to hæmorrhage from the mucous membranes. He regards this as a valuable symptom in early stages of the disease and has observed such a tendency in three cases out of six or seven. The cases recorded in his present article are as follows. Case 1. A woman of middle age observed after losing her teeth that hæmorrhages occurred from her nose and gums, vagina, and mucous membranes generally. She was accordingly admitted to hospital, in which she remained for 31 days, and during this time she suffered from three attacks of bleeding from the mucous membranes and large hæmorrhagic extravasations into the skin. She gradually improved under treatment and the hæmorrhages ceased entirely. Case 2. The patient was a young woman, aged 27 years, who suffered from similar hæmorrhages at the commencement of exophthalmic goitre. During her residence in hospital, extending over a period of five weeks, she had no less than six severe recurrent hæmorrhagic attacks. Both patients were subject to slight and commencing exophthalmos, and Dr. Popoff is inclined to include the hæmorrhagic tendency among the earlier diagnostic signs of exophthalmic goitre.

OBSERVATIONS ON TUBERCULOSIS IN ITS EARLY STAGES.

A NUMBER of interesting papers constituting a symposium on the above subject was presented by various physicians at the American Medical Congress held at Atlantic City, N.J., from June 5th to June 8th. Dr. J. M. Anders of Philadelphia stated that the pre-bacillary stage of phthisis was one of long duration and extended to the time when the bacilli had invaded the lungs and could be detected in the sputa. During this pre-bacillary stage diagnosis was to be made by three methods: (1) the use of the x rays; (2) the application of the tuberculin test; and (3) a careful study of the history, symptoms, and physical signs. Among the most important indications of the last class was a two hours' temperature record which would show elevation of temperature at a given hour daily. Dr. S. Solis-Cohen of Philadelphia stated that in the incipient stage of tuberculosis the time of the highest temperature was between 12 noon and 2 P.M., except in cases of inverse temperature. Dr. Victor C. Vaughan of Ann Arbor, Michigan, said that the temperature of tuberculosis in its early stages was more characteristic than that of typhoid fever, though many things might cause it to vary. Rest was one of the great benefits of sanatorium treatment. When the temperature was not high a moderate amount of out-door exercise might be indulged in. He further pointed out that many patients suffering from argyria as the result of the use of silver in the treatment of epilepsy developed tuberculosis. This view, however, was controverted by others. Dr. Delancey Rochester of Buffalo thought that the spread of the disease among tailors and seamstresses might in a measure be accounted for by the fact that they had a habit of wetting

the thread in the mouth. Dr. W. Freudenthal of New York City stated that in 1500 cases of tuberculosis present in persons following various occupations tailors were the most frequently affected, those who worked in "sweat shops" or who lived in dark, unventilated rooms being particularly attacked. Dr. C. P. Ambler contended that cases of pulmonary tuberculosis should not be reported as cured until a long time had elapsed. Thus of 46 cases classed as A 35 were regarded as cured. These numbers referred to the present condition of cases treated during 1898 which were reported at the annual meeting of the American Medical Congress in 1899. Again, of 28 cases classed as B six were apparently cured, and of 32 cases classed as C, nine were greatly improved. The treatment adopted was as follows: hygienic supervision, climatic influences, medication, and serum-therapy. Cases apparently cured under serum-therapy were less liable to relapse. Dr. Mayo of New York believed that no tuberculous patient would throw off the liability to the disease, no matter how long he might live, but if a tuberculous patient were relieved of his symptoms for a year he was practically well. Dr. Upshur illustrated the importance of hygiene by citing the case of the negro in the Southern States; when a slave he was practically free from consumption, but at present in the first and second generations since slavery was abolished the march of consumption was so great "as to warrant the feeling that the solution of the social problem lay in consumption," which bade fair to reduce the negro to the same unimportant position in the country as the Red Indian occupied.

SIR W. FOSTER AND THE MEDICAL ARRANGEMENTS AT THE SEAT OF WAR.

SIR WALTER FOSTER'S speech in the House of Commons on the occasion of the debate on June 29th on the treatment of the sick in South Africa does not seem to have been fully reported in the papers. He is stated by some who were present and had the privilege of listening to him to have made some statements which certainly appear to require elucidation, for, taken as they stand, they are calculated to raise the eyebrows of astonishment, as the Germans say. Sir Walter Foster is alleged to have stated that the opinion of the late Professor de Chaumont with regard to the provision of hospital accommodation for an army in the field was that it should be calculated at 25 per cent. As we have been unsuccessful in our attempts to verify this perhaps Sir Walter Foster would be kind enough to furnish a reference to the publication from which he obtained the record of this opinion on the part of Professor de Chaumont. He also stated that in his (Sir W. Foster's) judgment, had prevision been exercised and due provision made the case mortality of enteric fever might have been brought down to 12 per cent. Does he really mean to say that the mortality during a campaign should be less than what it is in hospitals at home where every agency for good is available? If so, he should lose no time in instructing the medical officers, not only of the British, but of all European, armies how this improvement is to be effected, especially under the conditions of war where the sick have in any case to be relegated from the front to hospitals in the rear. We think we recollect that it was the late Sir William Jenner's opinion that the movement of typhoid fever cases was injurious, in which we fancy most medical authorities would be inclined to concur, but this, to mention only one of the things incidental to war, is unavoidable. Moreover, Sir W. Foster seems to have implied or suggested by his remarks that medical officers are in the habit of recording enteric fever as "simple continued fever," with the object of minimising the number of cases of the former. He surely could not have meant this. That cases of enteric fever are occasionally so recorded is a well-known fact, but from no such motive as that implied. Not to mention such cases as are of a mild (ambulant) type, Sir W. Foster's experience must have been of an exceptional character if he has not encountered many in which the true nature of the fever is not (and cannot be) determined with any accuracy in the initial stages of the disease. As a matter of fact, however, it is a common practice among medical officers to regard and return every fever case with a rise of temperature lasting over six days as one of enteric fever. It is easy to understand, however, that as the subsequent "change of disease" (in the statistical returns) entails a certain amount of clerical labour in order to maintain the accuracy of the statistical returns (which members of the House of Commons, including Sir W. Foster, often call for), it frequently happens no doubt that the change is not made, especially in the hurry and pressure of war. But it is obvious that if a small proportion even of the cases of simple continued fever were returned as enteric fever the present death-rate of the latter would be reduced to that extent and be more favourable than it is. The present death-rate of 21½ per cent. may consequently be regarded as an extreme ratio, for it is capable of large discount seeing that simple continued fever is hardly ever fatal. As to what an independent authority in the shape of a small commission could have effected under the circumstances that obtained in South Africa we are at a loss to understand. From a sanitary point of view they could manifestly have done nothing until the British forces had invaded and taken a place, when their operations would have been too late, and they could not have delayed or altered any essential military operations, or prevented the army from altogether outmarching its supplies, or have increased the amount of available transport by rail, or otherwise prevented the enemy from making raids upon it, or fouling the rivers and sources of water-supply, or capturing the waterworks. They might no doubt have represented this and that and "intervened in regard to questions between military commanders and medical officers" if the theatre of war had been a small one or had they been ubiquitous; but could they have got up hospitals and supplies where needed without the means of doing so and would they not have been, in fact, the proverbial "fifth wheel" to an already embarrassed and overladen coach?

TREATMENT OF MEMBRANOUS COLITIS.

THE *Medical News* of New York of June 2nd contains a valuable paper by Dr. W. H. Thomson on the treatment of the very troublesome disease, membranous colitis. He finds that nothing is so soothing to the tenesmus as free irrigation of the colon with normal saline solution, to which may be added oil of peppermint, five drops to the pint. From three to five gallons at 100° F. may be used once in 12 hours with Kemp's rectal irrigator, care being taken that all the fluid returns. Once a week a pint of hot water containing from 30 to 40 grains of nitrate of silver may be used. But this irrigation is not curative, as it is in many cases of chronic catarrhal or ulcerative colitis. One remedy, Dr. Thomson finds, changes the disordered nutrition of the mucous membrane—castor oil in what he calls "alterative doses." He gives from half a drachm to a drachm of the oil in an emulsion either half an hour before or an hour after meals. This remedy should be continued for months and an intermission should be allowed only when the oil seems to increase the dyspeptic symptoms. Nitrate of silver in quarter-grain doses combined in pill or capsule with nine grains of turpentine resin, taken three times a day, is sometimes of much service. After six weeks sulphate of copper in quarter-grain doses may be substituted for the nitrate of silver. If dyspeptic symptoms exist five

grains of resorcin in solution with tincture of nux vomica may be given half an hour before meals and supplemented by 10 grains of sodium benzoate and 10 grains of bismuth salicylate in capsules an hour after meals as intestinal antiseptics. The chronic constipation (on which the disease depends) should be treated by salines. From one to two drachms of phosphate of soda with 10 grains of salicylate of soda should be given every morning in a tumblerful of water as hot as the patient can sip it. After a time the same quantity of sulphate of magnesium may be substituted. Daily massage of the abdomen is useful. As to diet beans, spinach, woody vegetables, and oatmeal, must be excluded, and the patients should be encouraged to take meat, poultry, eggs, koumiss, peptonised milk, and most cereals. Change of air in the country is the best remedy for constipation and it beneficially affects the disease. When all other means fail colotomy, as recommended by Dr. Hale White, may effect a cure.

THE PROPOSED INTERNATIONAL CONGRESS OF OBSTETRICS AND GYNÆCOLOGY IN LONDON.

THE publication of a *précis* of the proceedings relating to the proposed meeting of the International Congress of Obstetrics and Gynæcology in London in the current number of the *British Gynæcological Journal* has enabled those who were but imperfectly acquainted with the facts to form a fairly clear conception of the part taken by the British Gynæcological Society in this matter. It is greatly to be regretted that a perusal of the *précis* does not tend to show that the action of the Gynæcological Society was altogether free from blame. In view of the special nature of the relations existing between the Gynæcological and Obstetrical Societies the council of the younger society would have been well advised had they shown an earlier and greater desire for coöperation not only with the senior society, but, what is of far more importance, with those gentlemen who are the representatives of obstetric medicine in the medical schools of the metropolis. The summoning of an international congress to the capital of the British Empire should not be the work of any one society, however representative it may be. The fiasco which has resulted and which has unhappily only tended to accentuate the differences between the two societies, would never have occurred had the invitation to the organising committee of the Congress been sent, not by any one society, but by a committee representing the leading obstetricians and gynæcologists, not alone of London, but of Great Britain and Ireland. There can be no doubt but that under such circumstances both metropolitan and provincial practitioners would have loyally coöperated and the Congress could not have failed to be a success. Under the present conditions we trust that the Organising Committee of the Congress at their meeting on August 2nd will see that any attempt to hold a meeting in London in 1902 cannot but be a failure and will adopt the only course that at present appears to be open to them—e.g., that of postponing any such meeting in this city for some years. In the present issue of THE LANCET is published a letter from Professor Sinclair of Manchester upon the subject. As a leading provincial obstetrician and as a member of both societies he is able to regard the whole matter without prejudice. We would commend a perusal of this very temperate letter to the members of the Organising Committee of the British Gynæcological Society. As we have said, we believe the best method of promoting a meeting of the International Congress of Obstetrics and Gynæcology in London would be to form a provisional committee of the leading obstetricians and gynæcologists of England, Scotland, and Ireland. Such a committee could well include everyone of a representative character without regard to his official position in any society. With such a committee once called together it would be easy to settle details, to elect a president, and to appoint smaller committees to carry out the arrangements necessary to ensure the success of the Congress. The present unfortunate position is due to the fact that the Fellows of one society have thought fit to move in the matter in their capacity as representatives of that particular society. It is important to note that the meeting held at Dr. Playfair's house was not one of the Obstetrical Society, but of the teachers of obstetrics and gynæcology to the London medical schools, and that these gentlemen signed the letter refusing to take part in a Congress with regard to which important arrangements had already been made before their coöperation was invited in their capacity as teachers and not as Fellows of the Obstetrical Society. Professor Sinclair is clearly of opinion that the council of the Obstetrical Society were justified in the action they took in the matter, and although we must deeply regret that the necessity for any such action should have arisen, yet we fail to see how in justice to themselves they could have done otherwise. We trust when the time comes for again inviting such a Congress to meet in the metropolis that the present unfortunate occurrence will not be forgotten and that steps will be taken to prevent the possible recurrence of such an *impasse* as exists at the present time.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE fifty-ninth annual meeting of this association will be held in London on Thursday and Friday, July 26th and 27th, at the rooms of the association, 11, Chandos-street, Cavendish-square, W., under the presidency of Dr. Fletcher Beach, who will deliver his presidential address at 2 P.M. on the opening day. Following the President's address Dr. William Wynn Westcott, coroner for North-East London and president of the Society for the Study of Inebriety, will read a paper entitled "Inebriety, its Causes, Results, and Treatment." Dr. W. J. Collins and Dr. E. B. Forman of the Inebriety Committee of the London County Council are expected to speak. On the same evening the annual dinner will take place at the Whitehall Rooms of the Hôtel Métropole at 8 P.M., tickets one guinea each. On the second day papers will be read by Mr. H. Hayes Newington (member of the Sussex County Council and of the Asylum Committee); Dr. W. Ford Robertson, pathologist Scottish Asylums Laboratory, Edinburgh; Dr. J. Shaw Bolton (who will show some Naked-eye Preparations and Specimens from the museum of the Pathological Laboratory of the London Asylums at Claybury); Dr. David Orr, pathologist, Prestwich Asylum, and Dr. Thomas Philip Cowen who will read "A Contribution to the Morbid Anatomy of General Paralysis of the Insane." Dr. George A. Watson will exhibit some lantern slides to demonstrate Juvenile General Paralysis. Dr. J. O. Wakelin Barratt, pathologist, West Riding Asylum; Dr. John Turner; and Dr. Lewis C. Bruce, physician superintendent, and Dr. H. de Maine Alexander, assistant physician, Perth District Asylum, Murthly will contribute Observations upon the Various Physical Changes in the Acute and Subacute Stages of Melancholia. In the afternoon Mr. Cecil F. Beadles will read a paper entitled, "The Insane Jew"; and Dr. W. C. Sullivan, Dr. David Blair, Dr. A. F. Shoyer, and Dr. F. W. Edridge-Green will also read papers. It was agreed at the council meeting held on May 10th in London, after consulting the divisions of the association which reported unanimously upon the matter, that the following resolution should be placed before the annual meeting with a recommendation that a copy thereof be sent to the Local Government Board in the three kingdoms:—

"It is the unanimous recommendation of the Medico-Psychological Association of Great Britain and Ireland that

in union workhouses in which insane persons are detained a properly qualified and trained mental nurse should be employed in the insane wards."

On Saturday, July 28th, the President, Dr. Fletcher Beach, and Mrs. Fletcher Beach will be at home to members and their friends from 4 P.M. to 7 P.M. in the afternoon at Winchester House, Kingston-hill.

THE MEDICAL ACTS AMENDMENT BILL.

WE understand that Professor Sir R. C. Jebb has undertaken the charge of this Bill in the House of Commons. It has the support of the Privy Council and of practically all the universities and should not meet with any serious opposition.

OBSCURE LEGISLATION.

IN discussing questions relating to public health and local government we have frequently called attention to the obscurity of modern legislation, by no means confined to enactments in dealing with these topics, which arises from making one Act of Parliament incorporate by reference the provisions of another, instead of each statute being, as it were, self-contained. We are glad to see that Mr. Gibson Bowles, M.P., in a recent debate upon the Government Bill dealing with agricultural holdings called attention to this practice in forcible terms. The honourable member had apparently good reason to complain, for he stated that the Bill before the House was the most remarkable example of referential and allusive legislation he had ever come across, adding that no one could approach to an understanding of it until he had provided himself with nine other Acts of Parliament. As instances of the cross referencing of which Mr. Gibson Bowles complained he gave such passages as these, which will make clear to our readers the nature of the system against which we protest. "References to the Principal Act and to Sections 29, 30, 32 and 34 thereof shall be construed as references to the Agricultural Holdings Scotland Act (1883) and to Sections 24, 26, 25, and 30 thereof respectively." "Reference to manures in the Principal Act shall be construed as references to the improvements Nos. 24 and 25 in Part 3 of the first schedule of this Act." The House laughed at the sarcasms which the Member for King's Lynn levelled at a system of drafting which it has made its own, but it is no laughing matter for those who have to guide themselves by the light of such cryptograms in the fulfilment of public duties and who desire to do so without incessantly consulting their legal advisers as to the meaning of what need not be obscure. The system of legislating by cross reference instead of by printing sections in full may render a volume of statutes smaller and easier to handle than it would otherwise be, but to those who are not members of the legal profession lucidity in an Act of Parliament is of more value than a slightly diminished avoirdupois.

ARSENICAL PIGMENTATION AND KERATOSIS WITH ASCITES.

IN the *Johns Hopkins Hospital Bulletin* for April Dr. Louis P. Hamburger has recorded a case in which the above conditions were present. A man, aged 42 years, who had been taking for psoriasis from five to eight minims of Fowler's solution three times a day off and on for 10 years, came under observation. His illness began eight months previously with a "cold" and a cough. About a month later his abdomen began to swell and at the end of the day's work he noticed that his legs were swollen. The skin of almost the whole body was of a mottled yellowish-brown colour, small rounded areas of less pigmented skin alternating with more deeply-coloured parts. The face was slightly affected and the complexion was muddy. The hands and feet were not affected. On the palms the skin was diffusely thickened, and here as well as between the fingers were numerous dirty grey warts and callosities, varying in size from that of a pin-head to that of a pea. The soles were similarly affected. The abdomen was distended with fluid and the shins pitted on pressure. Thomas Hunt was probably the first who called attention to arsenical pigmentation. He wrote: "The trunk of the patient first, and, subsequently, all those parts of the body which are by the dress protected from the atmosphere, become covered with a dirt-brown, dingy, unwashed appearance."[1] Palmar and plantar keratosis were described first by Erasmus Wilson in 1868. In 1887 Mr. Hutchinson called attention to several cases and pointed out, further, that the use of arsenic might lead to the production of a peculiar form of cancer. Dr. Hamburger thinks that the ascites present in his case was also due to the arsenic, for Mr. Hutchinson has described a similar but more severe case in which paracentesis was performed three times and recovery followed only on discontinuing the drug.[2] In Geyer's report on an outbreak of arsenical poisoning due to contaminated water several similar cases are quoted.[3] The inference certainly seems justifiable and is, moreover, supported by analogy. For if ingested arsenic will irritate skin and mucous membrane, why not also serous membrane?

DISEASES WHICH SIMULATE APPENDICITIS.

THE difficulties of diagnosis in cases of supposed appendicitis are very great. Many other morbid conditions have been mistaken for inflammation of the appendix, and in some cases even an operation has been performed. On the other hand, real cases of appendicitis have been diagnosed as suffering from some other malady. In the *New York Medical Record* of May 26th there is a paper by Dr. E. J. Janeway of New York, which was read previously at a meeting of the Practitioners' Society, on "Some of the Conditions Simulating Appendicitis." We will mention a few of the principal cases which have come within Dr. Janeway's knowledge or about which he has been informed by physicians. Neuralgia affecting the lower abdominal nerves has in a number of cases given rise to doubt. In two cases in which operations had been performed the appendix was found to be normal and was not removed. In some the neuralgia was the reflexed pain of pneumonia or pleurisy. Another source of difficulty is in conditions of the right kidney, such as hydronephrosis and moveable kidney. Cholecystitis has in several cases been operated on from the belief that peri-appendicular inflammation existed. Ulcers in the gastro-intestinal tract, or catarrh with colic and cancer of the cæcum, have led to the belief in the existence of appendicitis. Fæcal impaction may be mistaken for exudation, and *vice versâ*. In a certain class of cases, not very frequent, a non-malignant ulcer of the hepatic flexure of the colon, with fæcal accumulation and possibly a moveable kidney, may mislead the inexperienced. An important fact is mentioned by Dr. Janeway that he has known the removal of the appendix to be done for the general aches and pains of follicular tonsillitis. It is only fair to add that he has been consulted in two cases of peritonitis from perforation of the appendix which were ushered in by follicular tonsillitis. Abscess of the ovary, retained menstrual fluid with sapræmia causing chill, or retro-peritoneal abscess may mislead. Hypochondriacal patients may fasten on the appendix as a source of evil and may receive the advice to have an operation immediately. Dr. Janeway's paper is of much value as drawing attention to the importance of an exact diagnosis in cases apparently

of inflammation of the appendix, and should serve to guard against every case of pain and tenderness in the right iliac fossa being looked upon as appendicitis.

NEALE TESTIMONIAL FUND.

WE are informed that this fund is about to be closed, but subscriptions received on or before Wednesday next, July 11th, will be included in the complete list which will shortly be published. We would remind our readers that subscriptions should be sent to Mr. J. Y. W. MacAlister, 20, Hanover-square, London, W., and it will save much trouble if cheques are made payable to "Bearer" and crossed "National Provincial Bank, Neale Testimonial Account."

STREET NUISANCES.

LONDON is such an unwieldy agglomeration of some dozen separate cities that coherent action is almost impossible. But the London County Council, which has after many complaints shown itself willing to do something to alleviate the sufferings of those who have to work with their brains, on June 29th held a conference with representatives of the vestries at Spring-gardens. A committee was appointed, to consist of one member from every local authority added to the sub-committee of the County Council, to discuss and report to a future conference upon matters which required definite regulations. The meeting then commenced to consider the removal of refuse and litter and we are glad to see that the case of Bond-street was specially mentioned for it is very narrow and between 9.30 and 10 A.M. in a disgraceful condition. This, however, as well as the question of street noises, was referred to the committee. We do not know whether the recently passed regulations upon "flash-lights"[1] were retrospective or not, but to mention only one of these, the intermittent advertisement at the top of Sloane-street is still hard at work or was so, at any rate, on the night of July 4th. Street-shouting, too, though the nuisance abated for some little time after the promulgation of the recent order,[2] is now, in the Strand at least, as bad as ever it was. The "runner" is not only a nuisance on account of his howling, but he makes great additions to the litter in the streets by dropping posters wherever he goes. Piccadilly-circus is a favourite dumping ground. Sir Edward Bradford issued a notice to the police to stop vendors from shouting, but their efforts have so far had singularly little result. The London School Board, too, might well spend a portion of the £2,000,000 or so which it extracts from the ratepayers in kidnapping the under-sized infants who shriek "cricket editions" at untimely hours. Only recently a maddened householder complained with success of the "terrible monotony of the cooing of a noisy animal, to wit, a dove;" surely the monotony of a newsvendor is far worse. However, relief seems to be visible in the distance.

IT is announced that the Queen has been pleased to confer the honour of Knighthood upon Mr. Riley Lord, the Mayor of Newcastle-upon-Tyne, and upon Dr. George Hare Philipson, the President of the University of Durham College of Medicine, Newcastle. Upon Mr. Riley Lord's unceasing and finally successful efforts to secure a new Infirmary for Newcastle we have already commented and we congratulate him heartily upon his good work and its well-deserved recognition. Dr. George Hare Philipson, besides being President of the University of Durham College of Medicine at Newcastle, is Professor of Medicine in the University and Lecturer on Medicine in the College of Medicine. In 1893 he was President of the British Medical Association. He is M.D. of the University of Cambridge and M.D., D.C.L., of the University of Durham, consulting physician to the Newcastle Infirmary, a Justice of the Peace, and representative of the University of Durham College of Medicine on the General Medical Council. His important and responsible position in the world of medicine has secured him many friends who will join with us in felicitating him upon the honour that he has merited and received.

IN our issue of June 23rd we gave a short account of the new pathological laboratories at Oxford and mentioned that last year an anonymous gift of £5000 had been presented to the University towards the erection of the buildings. The donor has now consented that his name should be made known and a decree is to be proposed on July 7th that the thanks of the University be conveyed to Ewan Richards Frazer, M.B., Balliol College, for his munificent donation. Dr. Frazer is a resident of Woolahra, Sydney, N.S.W.

THE honorary degrees of Doctor in Medicine and Master in Surgery of Dublin University were conferred on Sir William Mac Cormac, Bart., K.C.V.O., on June 28th. On the same day Surgeon-General J. Jameson, C.B., Director-General of the Army Medical Department, received the honorary degree of Doctor in Medicine. Both distinguished members of the medical profession were introduced to the Vice-Chancellor by the Orator, Dr. R. Y. Tyrrell, in speeches of excellent Latinity full of happy allusions.

DR. DANIEL JOHN LEECH, Professor of Materia Medica in Owens College, Manchester, died on July 2nd, in his sixty-first year. Dr. Leech represented Victoria University in the General Medical Council, and was Chairman of the Pharmacopœia Committee, but on account of illness was unable to attend the last meeting of the Council.

MR. FREDERICK TREVES, F.R.C.S. Eng., was on June 28th presented with the freedom of Dorchester, his native borough. Mr. Treves, in acknowledging the honour conferred upon him, alluded to the medical arrangements of the war in South Africa, and said that they could look with pride upon the work accomplished.

THE annual distribution of prizes to the students of the Medical School of St. Mary's Hospital will take place on July 13th at 4.30 P.M. The prizes will be presented by Dr. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge.

A TELEGRAM was received at the Colonial Office on Monday last, July 2nd, from Sir Henry Blake, Governor of Hong Kong, stating that 99 cases of bubonic plague with 98 deaths occurred in Hong-Kong last week.

THE annual meeting of the National Association for Promoting the Welfare of the Feeble-Minded will be held at Aubrey House, Campden-hill, W., on Monday next, July 9th, at 4 P.M.

THE appointment of Mr. John Sealy, M.D., as a member of the Legislative Council of the Island of Barbados has been approved by the Queen.

DR. L. S. JAMESON, C.B., has been returned unopposed as member of the House of Assembly of Cape Colony for Kimberley.

THE British Gynæcological Society will meet on Friday, July 13th, at Buxton.

WE are asked to state that the Cambridge Long Vacation Course will be given as usual.

THE WAR IN SOUTH AFRICA.

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

THE rumours which we have had for some days past that Pretoria had fallen into the hands of Lord Roberts are now officially confirmed, so that it is very unlikely that there will be any necessity for the continued presence of surgeons in South Africa, and in consequence I hope that this may be nearly the last, if not quite the last, letter that I shall have the opportunity of sending to you from Deelfontein. The heavy epidemic of enteric fever which has broken out will, of course, necessitate the keeping open of all the hospitals for a considerable time yet, and among them of this hospital. There are over 700 beds here now and we are just opening accommodation for another 200 patients in tents.

There is a rumour that the Yeomanry will be amongst the first of the troops to be sent home, and we hope to arrange to establish a hospital at Maitland camp which is just outside Cape Town, where they will mass in thousands previously to taking ship, and where in consequence there is sure to be a certain amount of sickness to be dealt with. We have, however, not yet heard what is to be the fate of the splendid institution here. It is such an ideal spot for a hospital, and so much time and trouble have been expended on drainage and sanitary works and on the elaborate system of water-supply as well as on the erection of the huts, that it will be a thousand pities if the whole is not taken over as a going concern by the military or the civil authorities and run for the permanent benefit of the large army of occupation that must be left behind or of suffering humanity in general. The alternative of repacking the 750 iron bedsteads and their hair mattresses and their bedding, and the accumulation of hospital paraphernalia and stores which go to make up a total weight of well over 1000 tons, and of transporting all of this nearly 500 miles to Cape Town and then 6000 miles to England, surely only requires to be mentioned in order to be avoided. The mere fact that nearly all the packing cases had to be used up owing to the scarcity of wood would make it an almost impossible task. Perhaps, however, it is early days yet for such considerations. There is still much sickness to be dealt with and we are very thankful indeed that the committee at home have sent out 10 more nursing sisters who will shortly be due in our camp, and in view of the large percentage of sickness amongst our staff will be extremely welcome.

The routine of work throughout the camp has settled itself down so satisfactorily, and every member of the staff does his or her allotted work so well, that everything goes on in a most peaceful and methodical manner, and it is difficult to realise that it is only two or three weeks since the end of those busy and bustling weeks of development and growth when one hardly ever had a quiet quarter of an hour. The cold weather, also, has brought changes which make life here more pleasant. It has killed all the flies, for one thing, and it has made the meat, about which I grumbled in a former letter, much more palatable, for now it is possible to hang it so long that when cooked one's teeth will go through it. This sounds a small thing in itself, but, as you know, it is very much easier to get work out of people when their food is good. The laundry is doing extremely well under Miss Cheesman's care, associated with whom is one of our medical staff, Dr. Bruce, who superintends all the disinfection of linen from the enteric fever patients and other infectious patients. Our carpenters, freed now from the work of erecting huts, are busy putting up shelves and cupboards and stoves for warming purposes as well as a lean-to just outside each hut, in which all the washing-up is done.

By the bye, we succeeded in reaching our full development of 700 beds, as in a former letter[1] I wrote that we hoped to be able to do, well within five months of the date of the appearance in the *Times* of the letter from Lady Georgiana Curzon and Lady Chesham suggesting the sending out of a hospital for the Yeomanry. I do wish that everybody who responded to that letter by subscriptions and gifts could come and see the hospital as it is now. There are very few things which I should try to hide from their gaze and perhaps the most important of these is the condition of the boots of the *personnel*. The fact is, that leather, except such as is specially prepared, perishes rapidly in this climate, and the combination of sand and boulders is not an amicable one for boot-leather; though indeed there are hardly any boulders to be met with now within the camp—they have all been collected by the natives for building walls or for making borders for the system of roads between the huts and the tents. The electric and other lamps which light the way in the streets of our small town exist only in the imagination of the newspaper correspondent whose description we have lately read in one of the London papers.

The smoking concerts continue to attract large audiences, but they take place now inside the large recreation tent which adjoins the church hut and forms the main body of the church on Sundays.

Two Roman Catholic priests and several medical men (both officers of the Royal Army Medical Corps and civilians) have been patients in our officers' wards. When they are well enough the convalescent officers come to our officers' mess. We have by far the biggest mess in the whole of South Africa, there seldom being less than 50 persons present at each meal. We are going to keep Christmas Day on June 25th, for that day will be midwinter, and last night we had a dress rehearsal in the shape of turkey and plum-pudding. It is really very cold now—there are several degrees of frost each night—and we have had to put an oil-stove or a coal-stove in each of the hospital huts.

It has been an unfortunate week for the Yeomanry, for, as you know, the Warwicks were badly cut up in the rebellious districts under Sir Charles Warren, and many of their wounded have arrived here, and then the 13th Battalion had the bad luck to get trapped at Lindley. By the time you get this it will be ancient history and you will know all about the latter misfortune. The only two members of the battalion who were not killed or wounded or taken prisoners are at present in this hospital—namely, an officer who has had enteric fever here but is now convalescent, and a trooper who, after the 13th Battalion of the Imperial Yeomanry (composed, as you know, of those very sporting companies the Duke of Cambridge's Own and the Irish Yeomanry) were surrounded on a kopje near Lindley, was sent to work his way through the Boer lines and fetch reinforcements from Lord Methuen who was in the neighbourhood. After a most exciting journey, partly on foot and partly on commandeered horses, moving each night and lying hidden during the daylight, this trooper got to Lord Methuen and conducted the reinforcements back to Lindley within the time that the officer in command of the Yeomanry had said that he could hold out for; but it seems that the Boers, whose numbers had grown each day from 500 to 2000, had brought some guns into action and had rendered the position untenable. It is a very sad ending for this fine regiment. I have seen a good deal of them since their arrival in South Africa a week or two after we came here, and indeed I travelled part of the way from Bloemfontein to Kroonstad side by side with them, and particularly noticed how well they scouted. I breakfasted in the latter place with them the very day that they set out for Lindley. They were then pointing out the good fortune that had attended their regimental number of "13." They mobilised in England on the 13th day of the month, and three times in South Africa it has happened that they have moved further up country on the 13th. They were such a splendid lot of sportsmen and had borne themselves so well through their more than usually rough time out here that I am sure everybody who knows anything of them will be extremely sorry for their bad luck in getting wiped out just before the end of the campaign; though considering the position they got into it is extremely fortunate that more of them were not killed, and I suppose it cannot be very long before those who were taken prisoners will be released. They will, of course, have lost every single thing they brought with them except the clothes the Boers leave them to stand up in. I think you will find that they will not have so much as a badge left between the whole lot of them, for this is the very first thing that the Boers loot, turning their attention first to the dead, then to the wounded, and then to any prisoners they may take.

Deelfontein, June 11th.

1. In addition to the male subordinates referred to in the table relating to No. 13 General Hospital dated War Office, 13th June, 1900, one special cook has since been despatched for duty with this hospital.

Medical Division, War Office, June 28th, 1900.

A CORRECTION.

A correspondent has pointed out an error which has occurred in one of our letters from the front. In THE LANCET of June 16th, page 1744, first column, three lines from the top, the "Washington-Lyons disinfector" is alluded to. The disinfector which was purchased by the committee was not a "Washington-Lyons" disinfector, but the Equifex saturated-steam disinfector, which was supplied by Messrs. J. Defries and Sons of Gravel-lane, London, E.C.

In the July number of *Science Gossip* is an interesting article by Major B. M. Skinner, R.A.M.C., medical officer in charge of the staff of the 6th Division of the South Africa Field Force, at present at Bloemfontein. It is upon the geology of the region traversed by the army during the march from Enslin to Bloemfontein. Major Skinner, who is a skilled geologist, describes the extraordinary appearance and formation of this inhospitable country. The article is illustrated by diagrams of sections.

THE ANTI-MALARIAL CAMPAIGN IN THE AGRO ROMANO.

As the first systematic attempt on a large scale to grapple with the problem of how best to combat malaria in the light of recent discoveries is about to begin in the Agro Romano the following translation of the instructions issued by the Bureau of Hygiene of Rome to the medical men who are to engage in this campaign will prove of interest. In view of the importance of this great experiment, and in order that the conditions under which it is being carried out may be better understood, we give these instructions in full. They are due, we understand, to the combined labours of Bastianelli, Gualdi, Postemski, and Dionisi.

GENERAL INSTRUCTIONS.

To the medical men stationed in the Agro Romana (*medici stazionari*) is entrusted the duty of preparing the work for the summer and autumn seasons before the arrival of the ambulances. They will coöperate with the ambulance medical officers (*medici ambulanti*) when the latter arrive, aiding them with that readiness and cordiality which ought to subsist between cultivators of the humane art in carrying out their common task. They will instruct their colleagues in such matters as the topography of the sanitary station and the position of the different farm-steadings, and proffer counsel and help in the difficulties which may be encountered both in the obtaining of servants and the procuring of the ordinary necessities of life.

Instructions for May and June.—1. The resident medical men will make an individual census of all permanent residents attached to the farms, as well as of their families. The particulars required of each person will be entered in the schedule for that purpose. 2. The schedule will be forwarded to the central office before June 15th. 3. The resident medical men will at the same time begin the treatment of all cases of relapses of malaria amongst these persons as well as among the mowers of hay and the reapers that may come to their knowledge, in accordance with the rule laid down in Table B (near the end.)

Instructions for July.—The ambulance medical officer, already informed by means of the schedule prepared by the resident medical man regarding the persons attached to the different agricultural and pastoral farm-steadings, will endeavour to become personally acquainted with the chief managers (stewards and factors) and the people in their charge, paying special attention to the cowherds, buffalo-herds, and horse-herds who are resident all the year through. He will commence the treatment of malarial patients and will continue it when begun by his colleague and advise as to the requisite prophylactic measures. A special table is given at the end showing the indications to be followed for treatment and for prophylaxis. During the first few days of the month begins the work of the threshing-floor (threshing of oats and wheat) directed by a manager who has under his orders the following persons—viz., one or two sub-managers, one overseer (foreman of the labourers), one herdsman, and sometimes also a herd-boy, a variable number of labourers (who attend to the transport of the sheaves of oats or wheat from the fields where it is reaped to the place where the threshing

machines are erected), one or two mechanics, one or two gangs of workers (consisting of from 30 to 40 persons for each threshing machine), one gang of builders of straw stacks, and one gang for pressing the straw. The ambulance medical officer will learn from the factor where and at what hour he can most conveniently see the foreman and labourers without disturbing their regular work. The hours most favourable for this are usually from 11 A.M. till 1 o'clock P.M. He will take notes in regard to each of the labourers (about the majority of whom he will already have information from the schedule drawn up by the resident medical man) on the schedule provided for the purpose, and of the conditions of health with respect to malaria. He will proceed actively with the treatment of all malarial patients, administering quinine in the manner indicated in Table B ("Treatment of Relapsing Fevers") and will give directions how infection is to be avoided as explained under "Prophylactic Measures." The labourers sleep in the open air as a rule for several hours at night, usually from 9 o'clock till midnight or 1 o'clock, and in the daytime generally from 12 to 1 o'clock. In regard to the quinine administered he will make notes in the diary annexed to the schedule. The majority of the labourers working at the threshing-machines, at the straw press, and at the building of straw stacks will be inscribed on their proper schedule, in which will also be reported the reply given by them to any questions. The relays of workpeople rest every four hours; the medical officer could therefore obtain the information he requires at 8 A.M., at 12 noon, or at 4 P.M. For these inquiries one day at each of the threshing-floors where the machines are at work should suffice. During the subsequent days the medical officer will inspect the threshing-floors, the cattle-farms, and the farm-steadings at such hour as he may deem most opportune, and he will keep accurate notes of the malarial relapses and of the primary attacks as well as of all therapeutic measures adopted. Every week a medical inspector will come to supervise the treatment in the interest of the patients. Towards the end of July the medical officer will obtain information from the overseers as to the number of the harvesters (men and women) who may have come to the farms and as to the place where they may most easily be found. Of these, also, he will make out a detailed list.[1]

Instructions for August.—During the first days of August the Campagna is nearly deserted. Farm work comes to an end and the more fortunate of the workers return to their homes while those who are fever-stricken repair to the hospitals of Rome. Some gangs engaged in the building of straw stacks or attending to the straw presses remain and a few men come to set fire to the stubble. The fixed population is represented by the overseer and by one or two labourers who reside permanently on the farm. The medical officer must keep a record of those remaining and of the new arrivals who are suffering from fever, treat those suffering from fever, and give all of them instructions as to the prophylactic measures to be observed. Those engaged in herding, who live on the cattle-farms, should be watched with especial attention. On farms where there are marshes marsh grasses are cut during this month. The workers are recruited from those who assist during winter and spring in the suburban vineyards and they remain on the farms for about a month. During this month, too, a supply of rushes is taken from the rush beds and the water-melons are gathered in; and on the sea-shore appear the tents of the mussel-gatherers who nearly all take fever. The medical officer will be able to collect accurate particulars from the overseers so as to follow up these various groups of workpeople who will nearly always require his services. Towards the end of August the labourers begin to return and farm-work gradually re-commences. The manager, the sub-manager, the overseer, the baker, and the mason, often with their families, all resume their avocations. It is indispensable that the medical officer should make notes in the schedules as to the condition of health in each individual case, both of those who have remained and of those who may return, that he treat all patients affected with fever, and that he give full instructions regarding prophylactic measures.

Instructions for September.—In September the work-people who reap the maize arrive. Amongst these will be found the greatest number of cases of fever; nearly all of the sufferers have taken part in the work of the threshing-floor, and some have left the hospital only a few days before. They sleep in the open or in small tents. The medical officer will fill up the schedules for each individual and generally carry out the same instructions as those given for the threshing-floor workers both in regard to treatment and to means of prophylaxis. The number of labourers now continues to increase, because from the first of the month onwards the work of preparing the soil for the sowing begins, while on some farms the first ploughing is now done. Besides the ordinary labourers some other workpeople, generally youths and boys, assist at this work, some of whom have come to the Campagna for the first time. Their task is to free the ground from obstacles which might interfere with the passage of the plough. It is possible for these people, if they choose, to sleep under cover. All the foregoing classes of persons must have their state of health inquired into and be made to adopt the measures enumerated in the tables.[2]

Instructions for October.—In this month, in addition to the fixed population, who all return so as to number the same as in the spring, gangs of workmen arrive (mostly from Aquila and Romagna) for the purpose of attending to the construction and repair of the canals or water-furrows, and bands of boys also come who look after the seed. These usually live in houses. The flocks of sheep gradually return in full number to the Agro Romano during October. The chief herdsman, the shepherds, and the other attendants looking after these number on an average about one to every 250 sheep. The medical officer will make a detailed list of these attendants; as a rule, by taking advantage of Sunday he will be able to accomplish this task in a few days, even on the large farms. He will do his best to obtain the adoption of the prophylactic measures recommended and he will attend to the treatment of the settled population and eventually also of the new arrivals.

PROPHYLACTIC MEASURES.

1. *General recommendations.*—Impress upon the workmen continually the advisability of never sleeping unless in closed shelters, houses, huts, tents, or under moveable mosquito nets. Even for a short nap during the day straw ricks and bushes are to be avoided.

2. *Recommendations to persons living in farm-buildings.*—Urge especially upon the manager of the farm whose circumstances will allow it the use of well-made mosquito nets. The ideal plan would be to fix in the windows wire nets painted white with meshes of two millimetres. Care must be taken at the same time that no mosquitoes enter by the doors, and that if they do they be destroyed. Distribute freely the larvicide powder,[3] pastilles, &c., to be burnt, with closed windows, every evening before bedtime. Hunt the mosquito constantly by burning damp straw, eucalyptus leaves, mint, or tobacco leaves in the room with windows closed; the mosquitoes lodge against window-panes or below the furniture, where they should be searched for and killed. It is useful to keep basins in the rooms with sugared water, especially where the mosquito net is used.

3. *Directions for persons living in huts and under tents.*—Numerous mosquitoes are apt to collect in the small huts of the encampments, the medical officer should therefore insist strongly upon prophylactic measures while the work of the threshing-floor is going on. The entrance to the tent should be furnished with a shutter of wire net, muslin, or linen. The inmates should sleep completely covered and perhaps wear a veil or special mask to protect more especially the head and hands. In the evening insecticide powders or pastilles should be burnt in the hut or under the tent. These will be supplied by the medical officer. Smoke thoroughly with damp straw or other suitable combustible material.

RULES FOR THE TREATMENT OF PRIMARY MALARIAL INFECTIONS.[4]

The administration of quinine in tabloids each containing half a gramme of the sulphate should be recommended

[1] The drawing up of this schedule must be done during the medical officer's visit, as it takes very little time.

[2] In the second half of this month the flocks of sheep belonging to the farms nearer the city begin to return to the Agro Romano from their summer pastures. When this happens the shepherds and other men employed on the pastoral farms should have due attention.

[3] Zanzolina (a mixture of "larvicide"—made by the firm of Weilerter-Meer, Therdingen—unopened flowers of chrysanthemum cinerari solium and valerian root); quantity, one or two spoonfuls. Also powdered chrysanthemum flowers with nitre, &c.

[4] These rules are given for the sake of obtaining a desirable degree of uniformity in the treatment, and do not pretend to formulate as yet a definitive method of treatment.

during the subsidence or at the end of the febrile attack. The quantity administered should be two grammes daily for three successive days and one gramme daily for other four days. Tabloids sufficient for a week's treatment are to be given in a small box with appropriate directions to each patient. After the remedy has been suspended for five days it will be well to follow the directions for relapsing cases even although there be no return of the fever. Hypodermic injections are only to be employed in exceptional cases. The medical officer is recommended to supervise the treatment of primary æstival infections in which the fever of the first attacks should be suppressed as far as possible, experience having proved the importance for prophylaxis of early treatment.

RULES FOR THE TREATMENT OF RELAPSING MALARIAL FEVERS.

The administration of sulphate of quinine should be carried out as follows:—

After the last febrile attack, or during its decline, two grammes of the quinine in four tabloids are to be given. The following day the same doses are repeated. During the next five days one gramme of sulphate of quinine in two tabloids is administered, after which the treatment is to be suspended for a week. The following week the administration is to be resumed, the patient being supplied with the same quantity of quinine as in the first week, and the quantity taken regulated as before. When the fever no longer returns the daily dose should be reduced by one half. The administration is then to be again suspended for a week. In the fifth week the same amount is to be given in the same way as in the third week, and so also during the seventh week. As a rule it is not necessary to continue the administration beyond the seventh week. During the weeks in which the quinine is suspended, he may, if he thinks proper, administer "Bacelli's mixture"[5] or capsules and tabloids containing iron.

For convenience of reference the above rules may be stated in the following tabular form:—

TABLES FOR THE ADMINISTRTION OF QUININE.

A. In Primary Malarial Fevers.

(Tabloids of 50 centigrammes.)

First	day (near end of febrile attack),	4	tabloids; total,	2	grammes.
Second	,, ...	4	,, ,,	2	,,
Third	,, ...	4	,, ,,	2	,,
Fourth	,, ...	2	,, ,,	1	gramme *
Fifth	,, ...	2	,, ,,	1	,,
Sixth	,, ...	2	,, ,,	1	,,
Seventh	,, ...	2	,, ,,	1	,,

Suspend the administration for five days, then continue as in Table B.

B. In Relapsing Malarial Fevers.

First	day (at end of febrile attack),	4	tabloids; total,	2	grammes.
Second	,, ...	4	,, ,,	2	,,
Third	,, ...	4	,, ,,	2	,,
Fourth	,, ...	2	,, ,,	1	gramme *
Fifth	,, ...	2	,, ,,	1	,,
Sixth	,, ...	2	,, ,,	1	,,
Seventh	,, ...	2	,, ,,	1	,,

Second week.—Suspend quinine; daily observations, &c. (in anæmic persons five tablespoonfuls of "Bacelli's mixture").

Third week.—Repeat treatment as in first week, but if no return of fever reduce dose by one-half.

Fourth week.—Suspend quinine; daily observations (in anæmic cases four tablespoonfuls of "Bacelli's mixture").

Fifth week.—Repeat treatment as in third week, with the same precaution.

Sixth week.—Suspend quinine; observations (in anæmic cases four tablespoonfuls of "Bacelli's mixture").

Seventh week.—Repeat treatment as in fifth week. End of treatment if no return of fever.

* If on the fourth day after commencing treatment the fever does not disappear continue with doses of two grammes. In exceptional cases use hypodermic injections.

Observations.—The treatment of the fever, whether primary or secondary, should be commenced according to the scheme laid down, even when the last attack has occurred some days previously. Whenever the fever asserts itself it is best to recommence the treatment as for the first day and to continue according to the rules prescribed. The total dose of quinine should be given within two hours—i.e., at intervals of half hour, three quarters of an hour, or one hour, according to the fractions. A glass of water should, if possible, be drunk after every tabloid, acidulated by preference with lemon or vinegar. In children the doses should be reduced in proportion to age.

Hypodermic and intravenous injections.—Hypodermic injections are reserved for cases of intolerance of quinine by the stomach and for cases of pernicious fever. In these cases two hypodermic injections are made, each of one gramme of the bi-hydrochlorate of quinine dissolved in five grammes of distilled and sterilised water. A large syringe is employed, the lateral regions of the abdomen being chosen and the skin washed with gauze and absolute alcohol. The needle should also be sterilised with absolute alcohol or by boiling in a test-tube. The hypodermic solutions in sterilised vials, each containing one gramme of bi-hydrochlorate, will be supplied to the medical officer. The patient must then be conveyed to the temporary hospital or to the city. In the hospital injections of camphorated oil and caffeine will be made. During the two subsequent days two grammes of quinine must be given daily either by injection or by the mouth (one tabloid of half a gramme every hour). The intravenous injections according to Bacelli's method will be made in extreme cases in the sanitary station hospital. For these injections boiled solutions of neutral hydrochlorate of quinine at a temperature of 40° C. should be employed exclusively in doses of one gramme in 10 cubic centimetres of chloride of sodium solution (0·75 per cent.).

[5] "Bacelli's mixture" contains the following ingredients: sulphate of quinine, 3 grammes; tartaric acid, 3 grammes; arseniate of soda, 5 centigrammes; distilled water, 300 grammes. The dose for an adult is one tablespoonful

ST. BARTHOLOMEW'S HOSPITAL AND CHRIST'S HOSPITAL.

FOR the past 15 years negotiations have been proceeding between the authorities of St. Bartholomew's Hospital and those of Christ's Hospital with regard to the former institution acquiring some or all of the land upon which the latter stands. Negotiations have now come to a dead-lock and on July 2nd a special court of the Governors of St. Bartholomew's Hospital was held to consider the situation. His Royal Highness the PRINCE OF WALES, President of the hospital, was in the chair and a full report drawn up by the treasurer and almoners was presented to the meeting. As this report was very lengthy, Sir SYDNEY WATERLOW recapitulated its main points in his speech as follows:—

As far back as the year 1885 the treasurer of Christ's Hospital wrote on behalf of his governing body stating that they would not fail to confer with the governors of this hospital in reference to the portion of their land which they desired to acquire. In the year 1890, after the constitution of Christ's Hospital had been revised, the new governing body resolved that negotiations be entered into with the governors of St. Bartholomew's Hospital to take as much of the Christ's Hospital site as they wished to have on the principle of arbitration with an umpire. We thus have the old governing body and the new governing body agreeing to sell us the land by arbitration. If this had been an agreement between two honourable commercial men there cannot be a doubt but it would have been regarded as binding, morally if not legally, but the governors of Christ's Hospital by their letter of November last entirely repudiate their agreement of 1893 and refuse to sell to us the land which we require for the enlargement of our hospital. The necessity for this enlargement is shown most clearly and distinctly by the letter from the medical and surgical staff dated November last in which they practically ask us to buy the whole site of Christ's Hospital. Personally I do not think that the purchase of the whole site would be a very speculative undertaking. ..... I hold in my hand the return of the sums available for hospital purposes during the last 30 years after paying all expenses. In 1869 our net revenue was £38,462, and in 1899 £72,454, or an increase of £34,000, thus nearly doubling our income in 30 years in face of great losses sustained upon many thousand acres of agricultural property in Essex, Lincolnshire, Kent, and elsewhere. Remembering that so large a portion of our property consists of houses and land in the great metropolis this increase is certainly worth at least 33 years' purchase and this would add £1,132,000 to our property in 30 years. ..... We cannot, I think, close this discussion without assuming for a moment that Parliament may not give us compulsory powers to purchase the land we require and that the governors of Christ's Hospital may not agree upon any terms that we can

accept. What position shall we be placed in? Well, it seems to me that we shall have but two alternatives, either to divide our work, separating to some extent the educational and scientific work from the nursing and treatment of sick patients. We possess some acres of small houses about a quarter of a mile north of this hospital where we might build a new hospital for some of the patients and where we might carry on the out-patients' work. This would be rather an advantage to the patients as the new hospital would be nearer their homes. If this course were not thought desirable there is another alternative. We might pull down all the older buildings, many of which are very dilapidated and the four blocks containing the patients. We should perhaps have to give up the church, the official residences, and the ground around them, and by rebuilding the hospital on modern lines with all the best modern appliances we could no doubt increase the accommodation from 30 to 40 per cent. Money could be borrowed. Let us try to imbue our hearts with the faith and hope which stimulated our great founder, Rahere, who in the year 1123, nearly eight centuries ago, started this hospital which from the beginning was "a hospital for the sick" and he, having no funds, begged at the new gate of the city for moneys to pay the expenses. Let his spirit stimulate us to go on to promote the prosperity of this old and Royal institution, always remembering that if we at any time feel obliged to appeal for more money we shall not make that appeal in vain.

A motion was then brought forward by Sir SYDNEY WATERLOW instructing the treasurer and almoners to adhere to the offer of £117,000 which had already been made for a portion of the site, and failing the acceptance of this that they should endeavour to effect a settlement upon the basis of the resolution of the Council of Almoners of Christ's Hospital which had been passed in December, 1893. Further, if neither of the above-mentioned alternatives should result in a contract to purchase, that Parliament should be applied to to obtain compulsory powers for purchase. This was seconded by Mr. WILLIAM FLUX and supported by the LORD MAYOR and Mr. G. BAKER.

The PRINCE OF WALES, before putting the motion, said that he only wished that the whole site could be bought, but that it was an absolute necessity that the one and a half acres should be acquired for which the sum of £117,000 had been offered. He trusted that the Charity Commissioners would back them up and that Parliament would not refuse. The motion was then put and carried unanimously.

There is but little to add to the simple statement made by Sir Sydney Waterlow. Everyone who has any acquaintance with St. Bartholomew's Hospital knows the urgent need for reconstruction and enlargement. The mortuary and post-mortem room are small, cramped, unwholesome, and quite inadequate for their purposes. The nurses' quarters must be reconstructed and rebuilt. The surgery is far too small and the college where the residents and students live consists of dark insanitary little houses. No one can blame Christ's Hospital for trying to get as much for their site as possible, but a promise is a promise and the authorities of Christ's Hospital have made a promise. Legal force it has none, but morally it is as binding as anything could be and if the almoners of Christ's Hospital break their parole it will not tend towards increasing public confidence in that body. A tyrannous king and an unscrupulous Minister did their best to ruin St. Bartholomew's Hospital when they laid sacrilegious hands upon the great priory of which the hospital had always formed a part, and although on the petition of the citizens of London the hospital was "refounded" and a beggarly pittance of 500 marks per annum given back out of its old revenues, it would be a fitting act for Parliament to step in and insure that Rahere's noble work shall not be again fettered.

THE SEWERAGE OF LEICESTER.

A LONG series of experiments, extending over some thirteen and a half months, upon the bacterial treatment of the sewage of Leicester, at the Beaument Leys farm, have at length been completed. They were carried out under the direction of Mr. E. George Mawbey, M.Inst.C.E., the borough engineer and surveyor. The results of these experiments have been printed in full in the form of a report to the Leicester Highways Committee and the Sewerage and Sewage Works and Farms Committee. This report is accompanied by a large number of coloured diagrams which enable the reader readily to see the analytical results and percentages of improvement arrived at by the several experiments, and besides these there are a plan of the sewage farm and district and many well-arranged analytical tables. The several analyses were made by Mr. S. F. Barford, F.C.S., whose method of working is given in an addendum. The undertaking throughout reflects great credit, not only upon the authors of the report, but upon all who have contributed to render such an inquiry possible. The publication will doubtless prove most advantageous as guides in future developments of the bacterial treatment of sewage.

Leicester has been for some time past in great difficulties with its sewerage system, arising not only from questions of level and the inadequate size of many of the sewers but from the very faulty construction of the older ones, which circumstances combined tend to establish a condition of things most detrimental to health. Owing to the defective sewers an enormous volume of subsoil water has to be pumped in addition to the normal flow of sewage. Many districts are flooded at times of heavy rains. This state of things, aggravated by the heavy character and limited area of the land available for irrigation, has led to the present inquiry. It is now proposed to reconstruct at least some 10 miles of the more defective sewers and to adopt a modified system of bacterial treatment in conjunction with one of irrigation. By these means it is hoped that the authorities will be able to deal effectively with the sewage and to comply with the requirements of the Local Government Board with but a slight additional increase to the present area of their sewage farm. The estimated outlay is placed at about £170,000.

The experiments were conducted with the following plant: (1) an open detritus tank; (2) a closed detritus tank; (3) an open settling tank; (4) the same tank as No. 3, made air-tight with inlets and outlets trapped and worked as a septic tank; (5) a first contact bacteria bed filled with coarse filtering material; (6) old pasture land and land laid out for rye grass for treatment of the effluent; and (7) a second and third contact bacteria bed filled with fine filtering material for final treatment of effluent irrespectively of irrigation. No trial appears to have been made of any anaerobic bacteria bed having an upward action. In the experiments at Finchley sewage farm in 1898 conducted by Dr. H. R. Kenwood, assistant professor of public health in University College, London, and Dr. William Butler a bed or filter of this description was found to be most effective in liquefying the sludge, the best results being obtained by a long rest in the filter. The actual amount of purification that took place was, however, limited. Mr. Mawbey doubtless had reasons for not instituting such a trial; in fact, he states that at Leicester they have no difficulty in disposing of the sludge. The period of rest required might also have proved a drawback to its adoption.

Space will not allow us to follow the many experiments in detail. They amounted to 17 in all. The detritus tank was retained in each case, being sometimes placed under anaerobic conditions. The other tank and beds were used in varying sequence. Briefly, the experiments tended to test four systems: (1) the septic tank system; (2) clarifying by bacteria beds only; (3) a combination of the septic tank with bacteria beds; and (4) a combination of bacteria beds with subsequent irrigation. The results of these experiments have led Mr. Mawbey to recommend his committee to adopt the combined system of bacteria beds with irrigation, forming No. 7 of his series of trials, and taking all the circumstances into consideration no doubt he is well advised in this course.

The following is a short description of experiment No. 7, which was extended over a period of 33 weeks. The crude sewage first flowed through the closed detritus tank, the effluent from which was discharged upon a group of clarifying bacteria beds each taking nearly an hour to fill. In these beds it rested for two hours, and a like period of two hours was occupied in emptying them. Each bed then remained empty for three hours; the entire process occupied about eight hours, thus permitting the beds to be filled three times during the 24 hours. The effluent was then allowed to flow once only over a plot of pasture for a distance of about 80 yards before being discharged into the dike leading to the river.

There were in all 28 sets of analyses made between

Dec. 2nd, 1898, and July 2nd, 1899, the averages of which given in grains per gallon, are as follows.

Matter in suspension.—Crude sewage, 43·7; detritus tank, 20·32; bacteria beds, 4·87; and pasture, 0·385. Final percentage of purification on crude sewage, 99·12.

Albuminoid ammonia.—Crude sewage, 1·182; detritus tank, 0·893; bacteria beds, 0·343; and pasture, 0·156. Final percentage of purification on crude sewage, 86·76.

Oxygen absorbed at 80° F. in four hours.—Crude sewage, 7·442; detritus tank, 5·795; bacteria beds, 2·145; and pasture, 0·663. Final percentage of purification on crude sewage, 91·08.

Nitrogen as nitrates.—Crude sewage, 0·044; detritus tank, 0·044; bacteria beds, 0·068; and pasture, 0·172.

Matter in solution.—Crude sewage, 73 05; detritus tank, 71·15; bacteria beds, 68·3; and pasture, 63·95.

Looking at these results the process of sewage purification is well exemplified. In the passage of the sewage through the closed detritus tank a larger percentage of improvement is seen to have taken place than is to be accounted for merely by sedimentation. A certain loss of chemical stability is evidently acquired which would most likely have been increased had the flow through the tank been still further retarded. The sedimentation was, however, considerable, and the smell from the sludge upon its removal from this closed tank is said to have been horribly offensive. In the aerobic bacteria beds, as might have been expected, the original details of the several analyses show that the amount of albuminoid ammonia and of oxygen absorbed varies greatly. This is of course also the case in the crude sewage, but in the several effluents the variation is also great in the proportional improvement effected, suggesting that at times the beds were being over-worked. It is well known that a bacteria bed of a given area is only capable of showing a certain improvement in its effluent in a given time from sewage of a fixed standard of strength; should this standard vary the character of the effluent varies accordingly. Mr. D. Scott Moncrieff, C.I.E., states that the best results are obtained from a filter when the strength of the sewage supplied to it is most constant. A perusal of the tables relating to the other experiments tends to confirm a previous suspicion—viz., that what is known as the septic tank system is only capable of a limited application. In large manufacturing towns with sewage conditions like those of Bradford, for instance, it might be likely to lead to disappointment.

At the end of the report are printed some interesting notes with illustrations of microscopical work by Dr. A. C. Houston relating to the experiments on London sewage at the Crossness outfall.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6592 births and 3368 deaths were registered during the week ending June 30th. The annual rate of mortality in these towns, which had been 18·0 and 14·9 per 1000 in the two preceding weeks, rose again to 15·1 last week. In London the death-rate was 14·5 per 1000, while it averaged 15·6 in the 32 provincial towns. The lowest death-rates in these towns were 9·0 in West Ham, 9·4 in Portsmouth and in Swansea, and 9·9 in Croydon; the highest rates were 18·1 in Halifax, 18·6 in Wolverhampton, 20·7 in Manchester, 21·3 in Salford, and 22·7 in Liverpool. The 3363 deaths in these towns included 419 which were referred to the principal zymotic diseases, against 427 and 366 in the two preceding weeks; of these 112 resulted from measles, 110 from whooping-cough, 70 from diphtheria, 55 from diarrhœa, 44 from scarlet fever, 27 from "fever" (principally enteric), and one from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Brighton, Portsmouth, Plymouth, and Preston; and the highest rates in Derby, Blackburn, Huddersfield, Sheffield, and Sunderland. The greatest mortality from measles occurred in Cardiff, Derby, Huddersfield, Hull, and Sunderland; from scarlet fever in Blackburn and Gateshead; from whooping-cough in Wolverhampton, Derby, Oldham, Sheffield, and Gateshead; from "fever" in Huddersfield; and from diarrhœa in Birkenhead and Blackburn. The 70 deaths from diphtheria included 29 in London, 10 in Sheffield, six in Leicester, and five in Liverpool. One fatal case of small-pox was registered in Salford, but not one in any other of the 33 large towns. There were 16 small-pox patients under treatment in the Metropolitan Asylums Hospitals, on Saturday last, June 30th, against 15 and 13 at the end of the two preceding weeks; eight new cases were admitted during the week, against eight and one in the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1832, against 1754, 1766, and 1810 on the three preceding Saturdays. 210 new cases were admitted during the week, against 203, 210, and 219 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 268, 257, and 181 in the three preceding weeks, further declined last week to 180, and were eight below the corrected average. The causes of 40, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bolton, Oldham, Hull, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Birmingham, Liverpool, Bradford, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·9 and 16·5 per 1000 in the two preceding weeks, rose again to 17·9 during the week ending June 30th, and was 2·8 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12·6 in Leith and 13·3 in Aberdeen to 21·9 in Perth and 25 8 in Greenock. The 552 deaths in these towns included 26 which were referred to whooping-cough, 24 to diarrhœa, 18 to measles, seven to scarlet fever, four to "fever," two to small-pox, and two to diphtheria. In all 83 deaths resulted from these principal zymotic diseases, against 78 and 60 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·7 per 1000, which was 0·8 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 21 and 18 in the two preceding weeks, rose again last week to 26, of which 23 occurred in Glasgow. The deaths from diarrhœa, which had been 22 and 19 in the two preceding weeks, rose again to 24 last week, and included eight in Glasgow, four in Edinburgh, four in Dundee, three in Aberdeen, and three in Greenock. The deaths from measles, which had been 23 and 14 in the two preceding weeks, rose again last week to 18, of which 11 were registered in Glasgow and four in Edinburgh. The fatal cases of scarlet fever, which had been six, six, and two in the three preceding weeks, rose again to seven last week, and included five in Glasgow. The deaths referred to different forms of "fever," which had been two in each of the two preceding weeks, rose last week to four, of which two were registered in Edinburgh. The two fatal cases of small-pox occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 106 to 87 in the three preceding weeks, rose again last week to 97, and were 20 above the number in the corresponding period of last year. The causes of 26, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·8 and 17·9 per 1000 in the two preceding weeks, rose again to 20·0 during the week ending June 30th. During the 13 weeks of the quarter ending Saturday last the death-rate in the city has averaged 25·4 per 1000, the rate during the same period being 17·6 in London and 19·0 in Edinburgh. The 134 deaths belonging to Dublin registered during the week under notice were 14 in excess of the number in the preceding week, and included three which were referred to the principal zymotic diseases, against 10, six, and four in the three preceding weeks; of these, two resulted from whooping-cough and one from diarrhœa. These three deaths were equal to an annual rate of 4·0 per 1000, the zymotic death-rate during the same period being 2·0 in London and 1·9 in Edinburgh. The mortality both from whooping-cough and from diarrhœa exceeded that recorded in the preceding week. The 134 deaths in Dublin last week included 19 of infants under one year of age and 33 of

persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons were slightly in excess of the number in the preceding week. Seven inquest cases and four deaths from violence were registered; and 38, or more than a quarter, of the deaths occurred in public institutions. The causes of eight, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Staff-Surgeon H. Holyoake to the *Vindictive*. Surgeons: G. B. Brown to the *Britomart;* J. W. Bird to the *Bramble;* J. O'Hea to the *St. Vincent* and G. M. Eastment to the *Excellent*, both lent during the manœuvres; G. E. Glynn to the *Vindictive;* and J. H. Lightfoot to the *Boscawen* for the *Wanderer*.

ROYAL ARMY MEDICAL CORPS.

Major F. M. Baker has joined at Woolwich for duty. Captain C. K. Morgan has been granted leave of absence out of India for six months on medical certificate. Colonel William E. Riordan is placed on retired pay. Lieutenant-Colonel James McNamara to be Colonel, vice W. E. Riordan.

MILITIA MEDICAL STAFF CORPS.

Ernest Urquhart Bartholomew to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Engineers: 1st Bedfordshire: Arthur Conning Hartley to be Surgeon-Lieutenant. *Rifle:* The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): Surgeon-Captain John Hugh Alexander Laing resigns his commission and is appointed Captain. 3rd Volunteer Battalion the Lincolnshire Regiment: James Matthews Duncan to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Worcestershire Regiment: Cecil Aloysius Corke to be Surgeon-Lieutenant. 1st Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Captain Charles Samuel Alfred Rigby resigns his commission and is appointed Captain.

TRANSVAAL WAR NOTES.

The first report of the American Hospital Ship (*Maine*) Fund for South Africa from Oct. 27th, 1899, to April 30th, 1900, has just been issued. Besides lists of subscriptions, donations, &c., it contains reproductions of photographs of Lady Randolph Churchill and her son, Surgeon-Lieutenant-Colonel Hensman and the nursing sisters, the surgeons, and the *Maine*.

Civil Surgeons R. B. Williams, W. J. Collins, and Pullin have embarked for South Africa.

Staff Surgeon E. P. Mourilyan, R.N., of the South African Naval Brigade, is returning to England invalided.

Major Whaite, R.A.M.C., Captain Dalton, R.A.M.C., and Lieutenant Cuddon-Fletcher, R.A.M.C., have left South Africa for England invalided.

Civil Surgeons Nicol, Goodman, and Thomas are returning invalided from South Africa.

The Welsh Hospital was ready for the reception of patients on June 1st. The huts, nurses, assistant surgeons, and 13 dressers and orderlies were sent to Springfontein on May 25th and on the last day of that month the late Professor T. Jones, Dr. Lynn Thomas, and Dr. Mills-Roberts arrived. The site of the hospital at Springfontein is 5000 feet above the level of the sea. Letters have been received in Cardiff from the hospital staff describing their quarters as "comfortable and almost luxurious." Patients too have written and spoken in high praise of the hospital.

Twenty nurses selected from the nursing staff of the London Hospital are being sent out to South Africa immediately.

The Prince and Princess of Wales have fitted up a farmhouse close to Sandringham for the use of officers invalided from the war who need convalescent help and have nowhere to go. This home in the first instance will be offered to colonial officers who will be considered as their Royal Highness's guests.

TRANSVAAL WAR CASUALTIES.

Civil Surgeon W. B. Bennett is reported dangerously ill in No. 1 Stationary Hospital, Mooi river.

Major Dodd, R.A.M.C., is seriously ill at the Base Hospital, Maritzburg.

ARMY MEDICAL SCHOOL, NETLEY.

The following is a list of Surgeons on probation of the Indian Medical Service who were successful at both the London and Netley examinations, June 30th, 1900. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley and the combined numbers are accordingly shown in the list which follows:—

	Marks.		Marks.
* 1. Graham, J. D. ...	6508	10. Macnee, H. R.	5017
† 2. Sprawson, C. A. ...	5875	**11. Deas, L. J. M.	4899
‡ 3. Mackelvie, A.	5495	12. Houston, W. M. ...	4875
§ 4. Lapsley, W.	5417	13. Keys, W. D. A. ...	4645
5. Cazaly, W. H.	5370	14. Young, G. J. G. ...	4534
6. Browne, P. A.	5354	15. Good, J.	4501
‖ 7. Coppinger, W. V. ...	5336	16. Chalmers, A.	4479
¶ 8. Spitteler, A.	5127	17. Hamilton, W. G. ...	4375
9. Oxley, J. C. S.... ...	5025	18. Godkin, S. R.	4314

* Gained the de Chaumont Prize in Hygiene, Hon. Mention in Surgery.

† Gained the Herbert Prize of £20, First Montefiore Prize of £21 and Medal, the Pathology Prize, and Hon. Mention in Hygiene.

‡ Gained the Second Montefiore Prize, and Hon. Mention in Medicine.

§ Gained the Parkes Memorial Prize, Martin Memorial Gold Medal, Hon. Mentions in Pathology and Surgery.

‖ Hon. Mention in Pathology.

¶ Hon. Mention in Medicine.

** Gained the Maclean Prize in Clinical and Ward Work.

Owing to the war in South Africa there was no public distribution of prizes. The prizes were privately distributed by Colonel K. McLeod, M.D. Edin., LL.D. Aberd., Professor of Military and Tropical Medicine.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals Thomas Walter Barrow (retired) at his residence at Woolwich on July 1st in his 83rd year. He entered the army in 1841 and served with the 2nd Queen's Royals in Scinde in 1843. In the Southern Mahratta country in 1844 he was present at the storming and capture of Fort Punella, and he took part in the campaign in the Concan in 1845, when Forts Monahur and Monsautosh were captured. He was also engaged in the Kaffir War of 1852–3. In August, 1864, he proceeded to Bermuda as Principal Medical Officer of a medical relief force in consequence of an epidemic of yellow fever which devastated the troops and population of the islands. For this service he was promoted to the rank of Deputy Inspector-General, the special General Order issued referring to his "highly meritorious services" in connexion with the epidemic. In 1865 he was appointed principal medical officer of Nova Scotia, and in 1866 to the same position at Woolwich and the London district. He retired in 1868.

THE CRISIS IN CHINA.

The following officers are reported as having been landed with Vice-Admiral Sir E. H. Seymour in North China:—Fleet Surgeon: T. M. Sibbald, H.M. battleship *Centurion*. Surgeon: E. D. Macnamara, H.M. cruiser *Endymion*. The *Jelunga*, No. 7 Transport, which left Portsmouth on Saturday, June 30th, with reinforcements for China, had on board the following medical officers:—Staff Surgeon W. E. Home (in medical charge); Surgeon A. Gaskell, Surgeon J. D. S. Milln, and Surgeon R. C. Munday.

Staff-Surgeon J. Mc C. Martin, D.S.O., R.N., and Surgeon N. Roche, have left for China in the P. and O. steamship *Australia*.

The *Jelunga* carries a large supply of field chests, medicines, surgical instruments, Roentgen ray apparatus, ice machines, surgical dressings and appliances, and all other necessaries, so that after discharging the naval force which she is conveying to China, if necessity should arise, she can be converted into a hospital ship on that station for naval purposes.

WARS: PRESENT AND PROSPECTIVE.

The Imperial idea and system are costing this country a large amount in blood and treasure at the present time. Setting aside the South African and Ashanti campaigns we have to take our part in the trouble in China, which promises to be, and is indeed already, a very formidable business. There will inevitably be a great demand for young medical men.

Correspondence.

"Audi alteram partem."

THE PROPOSED MEETING OF THE INTERNATIONAL CONGRESS OF OBSTETRICS AND GYNÆCOLOGY IN LONDON IN 1902.

To the Editors of THE LANCET.

SIRS,—It is a fair question for discussion whether international medical congresses are of any real service to medical science, but most of us will agree that they may be made pleasant and interesting. They may be even advantageous to individuals in enabling them to form correcting personal impressions of men whose published contributions to special medical literature they have been accustomed to read, and so to assess the value of their work. Assuming that these congresses are worth the trouble of organising, we shall be unanimous in professing to believe that they are the last class of medical assembly in the arrangements of which mere local dislikes and jealousies should come into play, or where places of honour, rightfully bestowed in recognition of distinction upon those most honoured by their countrymen who know them best, should by misadventure or mismanagement be conferred upon mere pushfulness and self-seeking. These reflections, and many others of a like nature, arise from the painful reading which you provided by the publication, in May this year, of the letters of the teachers of obstetrics and gynæcology in London and of the chief official representatives of the British Gynæcological Society anent the proposed International Congress of Obstetrics and Gynæcology to be held in London in 1902. But to all who take an interest in the progress of gynæcological science in England and are desirous of seeing British gynæcology held in honour by the medical profession throughout the United Kingdom, the feeling of pain and regret produced by the quarrel must be greatly deepened by a perusal of a "*précis* of proceedings relating to the proposed meeting of the International Congress, &c.," published in the last number of the *British Gynæcological Journal*. It is a summary of the proceedings of the British Gynæcological Society which culminated in the present unhappy position. Many men who are provincial specialists, or who specialise to the extent of being interested, are asking whether something cannot be done to relieve the tension and remove the deadlock between the two great societies in London, the persistence of which will entail a disastrous *fiasco* and a discredit to British gynæcologists in general if the present project to hold an international congress is not abandoned.

In intervening in the dispute and asking you to permit me to put certain considerations before your readers as a contribution towards the happy solution of existing difficulties I am not unmindful of the possible consequences to the candid friend. But after much cogitation I have reached the conclusion that certain circumstances call upon me to say something on the subject, and I respond to the call in the hope that some others, placed like myself outside the circles where personal considerations may unconsciously exercise a biasing influence, may be encouraged to come forward and lend the assistance of their opinions and advice. I have reason to believe that at the present time I am a member of Council both of the Obstetrical Society of London and of the British Gynæcological Society; I am also on the Council of the North of England Obstetrical and Gynæcological Society. These three societies between them cover the whole of England and to some extent overlap. Many provincial specialists are members of one or other of the London societies; some of my friends are, like myself, members of all three. I attended the International Congress at Geneva in 1896 and that at Amsterdam in August last. There were many opportunities of learning foreign and American opinion and of seeing ourselves as others see us. And these opportunities in my case were still further increased by renewing acquaintance with many American representative men at the congress of American obstetricians and gynæcologists at Indianapolis last September, and hearing their frank but friendly criticisms of the British *Fachgenossen*. Now, in the light of my own personal knowledge of American opinion, and remembering the importance of the American element in every international meeting, I am amazed at the want of consideration given by the Council of the British Gynæcological Society to the repeated spoken and written statements of Dr. Engelmann, president of the American Gynæcological Society, to the effect that "the invitation could be accepted only, and the Congress could be a success only, if the two great societies of Great Britain are united in their desire to see the Congress in their midst."

What then is the present situation? After this clear expression of opinion from the chief official representative of America; after the refusal of the Obstetrical Society to issue a joint invitation to the Congress; after the letter of the past and present lecturers and teachers of obstetrics and gynæcology in the London medical schools unanimously declining to promote or join the Congress; and even after the withdrawal of Professor Simpson from the position of president-elect on the ground that the Organisation Committee of the British Gynæcological Society was not sufficiently representative of metropolitan gynæcology, the council of the British Gynæcological Society still persevere in their unfortunate course. They have assured the permanent secretary of the Congress (Dr. Jacobs of Brussels) "that the Organisation Committee are anxious to do all they can to make the 1902 Congress a success and will continue energetically with the work they have commenced." Then they proceed to place themselves "at the disposal of the founders" and to give these foreign gentlemen the opportunity of reconsidering their acceptance of the invitation. Now, with all respect to my friends of the British Gynæcological Society I maintain that they thereby place themselves in an undignified, not to say ridiculous, position, and if they are as representative as they allege they drag British gynæcology with them. They reject the advice of friendly America, whose much-travelled representative men know us and understand us as we do one another, and they humiliate themselves before an unorganised committee of foreigners—a tribunal *pour rire*—who are notoriously and incurably ignorant of the personality and relative standing of British gynæcologists, and are separated from us by the gulf of alien ethical standards. Furthermore, there is a dilemma. If the invitation is still accepted the congress is bound to be a failure, perhaps as marked as that of Amsterdam, which was shunned by all Germans of distinction. On the other hand, if the invitation is not accepted after all, then the committee of the British Gynæcological Society bring upon themselves a snubbing which the consciousness of their singularly representative position must make all the more grievous and hard to bear.

In my humble opinion the Organisation Committee were in duty bound to make a stand, and in the exercise of their own judgment to come to a decision in this matter regardless of foreign influence. It is eminently a question for British gynæcologists and for them alone. If the actions of the Organisation Committee originated in disinterested public spirit (and how can it be otherwise?) they must seek to coöperate in bringing about a congress successful from both the scientific and social points of view, and they must desire to see in places of distinction on that occasion the colleagues whom *we in England* honour because of their character and work achieved. If this be so then the committee is bound to respond to unmistakeable expressions of opinion which are of weight beyond cavil, to hold all proceedings so far as quashed, to withdraw their invitation, and to join in a movement *de novo* towards the end in view.

The relations between the Obstetrical Society of London and the British Gynæcological Society are pretty well known and appreciated by provincial specialists both in their origin and incidents. But these relations, though largely responsible for the present situation, form too large and general a subject for discussion now. There have been, in the opinion of provincials, grievous faults on both sides. The refusal of the Obstetrical Society to coöperate with the British Gynæcological Society was perhaps too curt and unqualified, and is to be regretted. But those who know the history of the relations between the two societies must feel that, until men have developed a saintly meekness almost incompatible with vigorous action, no other result was to be expected. The Obstetrical Society has never received much encouragement to take part in the proceedings of the International Congress. Members of an inner circle of the British Gynæcological Society have been too frequently nominated, as the best that England could produce, to introduce or take prominent places in the official discussions, and

these have not seldom been men who would never have been selected as representatives by any conceivable parliament of British gynæcologists.

I remember well the presentation of the invitation from Great Britain to the Congress at Geneva. The deputation consisted essentially of two official members of the British Gynæcological Society who were notoriously antagonistic to the Obstetrical Society. And it should be remembered that the invitation presented at Amsterdam was merely a renewal of that given at Geneva. Dr. MacNaughton Jones and his colleagues appear to think that they play a trump card when they call attention to the fact that the invitation was presented at Amsterdam by Dr. Robert Barnes. Still, men have an awkward way of looking at the true inwardness of things, and not at mere formulæ; and the result of that honest examination of the situation was the remonstrances from America and by no means cryptic hints from many other quarters, as to the need for a working arrangement with the Obstetrical Society. These hints were ignored until it was discovered that arrangements which could be made apparently to succeed at meetings in foreign capitals would not suit a congress held in London. Hence, obviously, the too belated proposal of coöperation made to the Obstetrical Society. In some journals which have been sent to me I regret to read injurious references to the action of the lecturers and teachers of obstetrics and gynæcology of the London medical schools. Epithets are not arguments which tend to conciliation. The unanimity of these teachers and their dignified expression of refusal to take part in a congress for which important arrangements had been already completed is an impressive fact which should form food for reflection, not a subject for reviling and sarcastic levities.

The question still remains: Can anything yet be done to put British gynæcology in its proper place in the opinion of the specialists of Europe and America, and to bring about some time the holding of a creditably successful International Congress in England? As a provincial specialist knowing the opinions of many men similarly situated, who, like myself, are not conscious of envy or jealousy even towards London colleagues, I would submit that the time has long gone by when London societies could justly arrogate to themselves the right to speak for British gynæcology. Any truly representative body must have a wider basis. To be practical I would suggest something like the following, if the game be generally thought worth the candle. Let the honorary secretaries of all the existing Societies of Obstetrics and Gynæcology in the United Kingdom of Great Britain and Ireland form a convening committee to start with. It should be the function of this committee to form a grand committee of the members of these societies. Each of the societies could send a sufficient number of delegates to a meeting in London or elsewhere, as might be agreed, to elect an executive committee, or themselves to form an executive committee, to deal with the question of an international congress and other matters. If from this movement a great comprehensive society, on the model of the German Gynæcological Society, were to take shape and development so much the better. It would be premature to suggest further details. If among the specialists in obstetrics and gynæcology of the United Kingdom there is sufficient goodwill the way will be found.

I am, Sirs, yours faithfully,

Manchester, June 30th, 1900. W. J. SINCLAIR.

"THE RELATIONSHIP OF MALARIA AND THE MOSQUITO."

To the Editors of THE LANCET.

SIRS,—The interesting letter by Dr. Dauber in THE LANCET of June 23rd (p. 1834) requires a rather full reply, as his opinions are certainly shared by a considerable number of medical men, both in this country and the tropics. I trust that you can allow me sufficient space to deal with his arguments in some detail.

While admitting that "mosquitoes may frequently act as alternative or intermediary [he means *definitive*] hosts with man of the malaria parasite," he demurs to the dogma that the bite of *Anopheles* constitutes the only mode of infection. I should say at once that no one can as yet be *absolutely certain* that there is no other mode of infection. We differ only as to the degree of probability which attaches to the hypothesis that there is another mode of infection. Koch and the Italians think that there is very little probability at all in favour of this view. Manson and Laveran are more inclined towards it. Your correspondent, with many others, tends to the other extreme and still believes in the miasma *plus* the mosquito. Speaking for myself I must confess that I think it extremely unlikely that there is another route of infection besides the bite of the mosquito; I have met neither with facts nor with what appear to me to be sound arguments in favour of such a thing; while there are many extremely cogent arguments against it. At the same time I keep a perfectly open mind on the subject, and am quite willing to be converted by any good evidence which may be adduced in the future.

No one accustomed to sifting scientific evidence will, I fancy, be quite prepared to accept Dr. Dauber's. In order definitely to prove that a given outbreak of fever is not due to *Anopheles* it must clearly be shown that *Anopheles* were not present when the original infections occurred. It must also be certain that the cases of fever under consideration were first infections and not relapses; and, of course, that the disease was really malarial fever is a point which must have been established by microscopical methods before the case can be admitted into court. But your correspondent gives no precise details of this nature. He talks about "fever" and "swarms of mosquitoes" without specifying what fever and what mosquitoes. His instances appear to be based on very indefinite information. Even if his facts be admitted they often point in just the opposite direction to what he supposes, while he himself seems to think that popular impressions carry the force of experimental evidence. I will take his instances in the order in which he gives them. He quotes in support of his opinions a medical work in which "a chill, a wetting, the turning over of virgin soil, exposure, and fatigue are credited with causing fever as well as direct infection from mosquitoes." I hope that this medical work did not intend to imply that a malarial infection, a parasitic invasion, can be caused by a chill. One might as well say that round worms are produced by a chill. What I suppose the medical work really means is that a *relapse* may be precipitated by a chill, by fatigue, and so on—a thing with which we are familiar in many diseases and which has nothing to do with the original entry of the infecting parasites. I will deal later with the case of the "virgin soil." Dr. Dauber then proceeds to quote a writer in the *Times* who talks about the insalubrity of Pretoria and thinks that "the miasmas at sunset, attended by a bone-piercing cold, are especially dangerous." This is no evidence. The writer in the *Times*, voicing the popular idea, may believe in miasmas if he likes; but this does not go far to prove that they exist. What investigations has the writer in the *Times* made on the subject? As a matter of fact he seems to think that the miasmas arise from the "filthy habits of the genuine Boer"—a novel source for malaria. The writer in the *Times* may be Brown, Jones, or Robinson—the question is whether he knows anything at all about the matter. Next, your correspondent discusses the immunity which is supposed to be enjoyed by those who sleep at some height above the ground. He refuses to accept the explanation given by the theory that the mosquito is "a low flyer," because his own experience is opposed to this theory. Here we have a simple clashing of observation. The Italian observers—as well as myself—who have all been making a special study of mosquitoes for years, are quite convinced that mosquitoes often do prefer ground-floors to upper storeys. Apart from this, the question whether such immunity really exists is open to discussion. I fear we can hardly accept the authority—which Dr. Dauber quotes—of Kingsley's novel of "Westward Ho." If, as your correspondent adds, landing-parties in the navy "are instructed to make elevated platforms with boughs on which to sleep, and are supplied with axes for the purpose," this proves nothing. I have never known Government medical regulations cited as being medical authority of any value. Personally I should prefer the authority of "Westward Ho."

In British Guiana, Dr. Dauber says, "Young men freshly arrived from the temperate climates, although they would be bitten more voraciously than the older residents, yet were not very liable to malarial fever until they had resided about a year in the country." This is a most unfortunate argument, because, like the Irishman's pig, it goes in a precisely opposite direction to that which is intended. Obviously the longer a man has resided in a

mosquito country the greater the number of mosquito bites from which he has suffered from the commencement of his stay there, and the greater therefore his chances of having been bitten by an infected mosquito. If only one mosquito in a thousand is infected (which is quite possible), a man may well reside a year in a place before meeting his fate. On the other hand, if the poison lies in the soil, why are not these young men all infected the moment they land? Dr. Dauber thinks that "fresh arrivals bitten from head to foot and living amongst men constantly down with fever" should become infected at once; he again omits to note whether he refers to the bites of *Culex* or *Anopheles*.

A number of instances are given where malarial fever was supposed to be due to turning up "virgin soil." These are of the usual indefinite kind. Was the fever malarial fever (and not, for instance, ankylostomiasis—which is an earth-borne disease, and is frequently mistaken for malaria)? Were the cases original infections and not relapses due to chill and fatigue caused by the labour? Were *Anopheles* certainly absent? These questions must be answered before the evidence is worth a straw. It is no use quoting Mark Twain and describing public impressions at the time. Dr. Dauber adds that while the troops engaged in excavations at Hong-Kong suffered greatly from malaria the "Argyll and Sutherland Highlanders also stationed there at the same time, who were not engaged in the excavation works, did not suffer similarly"; and he continues with the remark that "It is hard to believe that the mosquitoes could make a differential diagnosis between the Engineers and the Highlanders." Certainly this would be hard to believe if the Engineers and the Highlanders lived intermixed in the same barracks and slept in the same rooms. Are we to understand that this was the case? If not, where is the point of the remark? Everyone who knows anything of the matter is aware that there may be crowds of *Anopheles* in one house or barrack and few in the next (as at the Wilberforce barracks in Sierra Leone), or none at all a few hundred yards away. Your correspondent seems to imagine that mosquitoes are a uniformly diffused entity like a gas. It is quite possible that the Engineers lived in sheds or houses infested with *Anopheles*, while the Highlanders did not; at least this point must be settled before the instance is of any value at all as evidence. Dr. Dauber's reference to the general paucity of mosquitoes at Hong-Kong is rather unfortunate in view of the recent find of *Anopheles* there by Mr. Ladds. His attempt to dispose of their breeding pools by quoting the words of an Engineer officer who says that no pools remain after heavy rain, is also scarcely what we call scientific evidence nowadays, and is moreover summarily discredited by the work of Mr. Ladds—to which I refer your correspondent. Then he quotes an officer of the Ashanti expedition of 1873–74 to the effect that in those parts "there is any amount of malarial fever but practically no mosquitoes." Really, this is the old old story. It was like the story I was told—and by a medical man too—that there are no mosquitoes in Sierra Leone! During the last few months I have heard the same absurd statement about every town on the West Coast of Africa, the fact being, of course, that many people never observe anything at all, not even a mosquito bite. Your correspondent next relates the case of a hospital ship, the *Simoon*, on which after a time malarial fever became endemic, infecting, for instance, the wounded returning from the expedition just mentioned. The *Simoon* was condemned and replaced by the *Victor Emmanuel* which remained healthy. "If mosquitoes were the means of conveying infection in the first vessel," exclaims Dr. Dauber, "why were they not also in the second?" Possibly for the simple reason that there were no mosquitoes, or at least no *Anopheles*, in the second vessel. It must surely be remembered that *Anopheles*, like many other insects, have their seasons. Moreover, the same case would tell equally against the idea that the malaria lay in the air of the locality in which the two vessels were stationed.

Next we hear the case of H.M.S. *Active*, from which a punitive expedition was sent up the Niger in a steamer. The expedition remained quite well until it returned to the *Active*, which then put to sea. Within a week after she had put to sea "nearly all of those who had taken part in the expedition were down with fever of a severe type." What point is there in this story? Dr. Dauber seems to forget that in malarial fever, as in other diseases, there is an incubation period—lasting up to three weeks. I suppose that the members of the expedition were infected before they returned to the *Active* and that the disease appeared in them some time afterwards—that is all. The case appears simple enough. Unless, indeed, the members of the expedition brought some freshly turned virgin soil with them I do not see that it applies to the question at issue. How explain it better on the supposition that malaria exists in the ground, for instance?

The disappearance of malarial fever in England affords your correspondent another text—since mosquitoes, even *Anopheles claviger*, remain in England (which is true) how is it that the fever has disappeared so entirely? Precisely, and the answer gives perhaps one of the most serious blows to the soil theory. It is very well to talk largely and vaguely of the effects of drainage of the soil in England, but let us inquire more particularly. Are we to suppose that every square yard of soil in England has been drained? I suppose that there are a *few* ill-drained fields and ditches still remaining even in England. If so, why have the parasites which by hypothesis live in such places gone so completely? Surely there must be a patch of soil here and there which still contains its hordes of malaria germs. Surely a chance labourer may now and then happen to dig in such spots of ground, and should therefore contract the disease. It will not do; if the germ ever lived in British soil it is most highly improbable that it could have vanished so rapidly and completely as it has vanished. On the other hand, the mosquito theory affords a simple explanation of the phenomenon. According to it both *Anopheles* and malaria cases must be in sufficient numbers for the former to have a reasonable chance of becoming infected from the latter. But what has happened? The fever cases have been consistently reduced with quinine, while simultaneously the *Anopheles* have been reduced by drainage. The chances are now thousands to one against an *Anopheles* ever biting a person suffering from malarial fever in England—more probably millions to one. But I will not anticipate some important researches which I hope will shortly be published on the subject.

Your correspondent does not think that the mosquito theory sufficiently explains the connexion of malaria with rainy seasons or rank vegetation. That is a mere matter of opinion. He says that though mosquitoes teem up the river Parana in South Africa—mosquitoes *probably* of all kinds—yet fever is little prevalent there. This is not definite enough: we must know for certain that *Anopheles* do not exist at the exact spot where malaria prevails before the evidence has any validity. He avers that an offshore wind can induce an outbreak of malarial fever in vessels lying 50 miles from land. The records of such cases would be interesting ones, and I hope that your correspondent will find the time to publish them. Until then we must be excused if we scarcely admit with Dr. Dauber that such instances "prove conclusively that the atmosphere has some intimate connexion with the disease." He adds that he finds it difficult to explain on the mosquito theory how "it is only the *land* breeze which does the mischief." Admitting the statement (which may, however, be doubted) I suppose it may be explained on the ground that the land breeze is more likely to carry the mosquitoes from the land to the ship than is a wind in the opposite direction. Lastly, he says that the paludal, miasmatic, and telluric conditions are still believed in in the British navy. I do not doubt it; they will doubtless be believed in by the British navy for the next hundred years.

I have now examined, I think, all of Dr. Dauber's instances and arguments and have done so at such length chiefly because similar views are continually being expressed by medical men in spite of all refutations. Such views appear to me to have a certain old-world flavour about them—smacking of the pleasant days when direct observation and experiment were not yet necessary in medical science, when we based our conclusions on obsolete text-books, hearsay evidence, and travellers' tales, and when a medical man could gain a reputation in tropical medicine on the strength of possessing a stuffed crocodile in his consulting-room. I do not mean to say that all such views are wrong, but certainly all of them are not right, and what I wish to impress is that they have little value as scientific evidence in the sense in which we now understand it. If the malarial miasma really exists its existence must be demonstrated not by citations of popular beliefs but by exact scientific work. Meantime our position is quite clear. Dr. Dauber blames us for inculcating the destruction of mosquitoes and so on without reference to precautions against the miasma. But this is quite logical. We are sure that *Anopheles* communicate the

disease and we therefore devise measures against them. We know nothing for certain about other modes of infection and we therefore refuse to advise precautions against them. We cannot accept popular beliefs as being in any way equivalent to scientific demonstrations.

As a matter of fact, your correspondent has quite overlooked (although he nearly touches it once) the train of argument which is most fatal to the miasma hypothesis—I mean the arguments based on comparative parasitology. We are now familiar with a very large number of animal parasites and we recognise that their development and life-history proceed in accordance with certain general laws. Those which, like the parasites of malaria, pass between alternate hosts, possess a complicated development which enables them to do so. But there their develcpment ceases. They do not also possess properties or organs which enable them to live in half-a-dozen other media as well. The life-cycle of the parasite of malaria is already complete according to these biological laws, and we have no justification for supposing that it possesses other life-cycles fitting it to live in the soil, or in the marsh, or in the air. We may as well suppose the same thing of tapeworms or trichinæ. The idea that any parasitic organism breeds indefinitely, say in the soil of an uninhabited locality, ready to pounce out upon the first man who happens to dig there, is a zoological absurdity. Moreever, the method of inoculation which nature has discovered for the malaria parasite is so simple and yet efficacious that those who have studied the wonderful arrangements by which it is brought about are not disposed to look with much favour on the clumsy ideas of the miasma and the telluric emanation. I am, Sirs, yours faithfully,

Liverpool, July 1st, 1900. RONALD ROSS.

P.S.—Dr. Dauber's reference to the Parana river region, where mosquitoes "teem in their millions and billions" and yet malaria is so uncommon, seems more unfortunate than I suspected at first. I wrote on the subject to Mr. F. V. Theobald, of the British Museum, who is collecting the known information about mosquitoes, and have just received the reply which he was kind enough to send me. After mentioning the species of *Anopheles* found in that region, he adds: "This is all I can recall. It would thus seem that *Anopheles* are not common in those parts of South America—very different to what we find in the Malay Peninsula, West Coast of Africa, India, &c."

"THE NATIONALISATION OF TRINITY COLLEGE, DUBLIN."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 30th a correspondent over the signature "A.M., M.D., Dub. University" writes: "Although I am unable to discern that the columns of a medical journal are the proper arena for the discussion of the Irish Catholic University question I feel bound to contest your conclusion as set forth in an annotation in THE LANCET of June 23rd, p. 1815, that the proposal to nationalise Trinity College is 'as useless as it is impracticable.'" Now if your correspondent will look again at the annotation he refers to he will see it is entitled "Irish University Education"; that is, the paragraph deals with the question of Irish University education as a whole and not merely with that portion in which Roman Catholics are specially interested. Further, in the discussion of university questions whether they affect the whole or only a portion of the inhabitants of a country, your readers must admit that the interests of the medical faculties, which now constitute such large and important departments of all universities, demand most careful consideration; and where can questions affecting these medical departments be more appropriately discussed than in a medical journal of such great influence and with such a wide circulation as THE LANCET?

Your correspondent takes a very narrow view as to what is meant by the nationalisation of Trinity College, Dublin. He defines it "as the complete de-sectarianising of it"; and he thinks the whole question would be settled if some Government would "proceed to eradicate all traces of sectarianism from the University of Dublin. To effect this latter purpose it would be essential to transfer in its entirety the Divinity school of Trinity College to the outside custody of the Church of Ireland, with a grant to that Church equivalent to that now made to the sectarian education at Maynooth and elsewhere." No doubt, from a Trinity College point of view, this solution of the Irish University question would be an admirable one; that is, Trinity College would continue as it is with the exception that the Divinity school would be transferred to the care of the Church of Ireland and would receive a grant equal to that of Maynooth. In other words, Ireland would possess a new Divinity school for a minority of Irishmen endowed as largely as Maynooth which educates theologically the clergy who minister to the wants of three-fourths of the inhabitants of Ireland. The Divinity school, separated from Trinity College, would thus become one of the most richly endowed theological institutions in the world. Would the British tax-payer calmly submit to pay as much for the education of the clergy for a population of 600,830 members of the Church of Ireland as for 3,549,745 Roman Catholics? Or, to put it in another way, is the theological training of the clergy of 12·8 per cent. of the population of Ireland to cost as much as that of 75·4 per cent.?

But, Sirs, does your correspondent imagine that if Trinity College was desectarianised in the way he suggests the Irish University question would be at all settled? As everyone knows, it is a cardinal doctrine of the Roman Catholic Church that its members accept the teaching of their ecclesiastics as to what is dangerous to faith and morals. The removal of the Divinity school from Trinity College would still leave what your correspondent describes as a "thick Protestant atmosphere" in that place which the Catholic Church teaches is inimical to the faith and morals of her sons, and hence Trinity College would be as much as ever under the ban of that powerful religious organisation.

There is, however, another and most important factor which your correspondent entirely ignores and which will have to be considered in any proposed settlement of Irish university education. If Trinity College is nationalised, not merely in the limited sense of having its Divinity school removed, and becomes a secular institution, how will this change meet the existing state of affairs as it concerns various Colleges and educational centres in Ireland outside Trinity College, what will then be the position of the Queen's Colleges of Belfast, Cork, and Galway, of Magee College, Derry, and of Victoria College, Belfast? How are these great educational institutions to be dealt with in this national university? Are they simply to send their students to Trinity College, Dublin, and close up their halls, or are they to remain as at present, let their students go to Trinity College, Dublin, for examination, and have no share or voice on the governing senate of this new national university? Is the great medical school of Belfast, one of the largest in Ireland, situated in a rapidly increasing city whose population now exceeds that of Dublin, to be quietly absorbed and take a subordinate position in this new national university? Does your correspondent really imagine that in these days of decentralisation, with new universities such as the Victoria, Birmingham, the Welsh, and the London, the hands of the clock are to be put back, and in Ireland everything of an educational nature is to be controlled from Trinity College? Is that institution to be the only place of collegiate education for young Irishmen, and, if so, how are the institutions already existing, such as the Queen's Colleges, Magee College, and Victoria College to stand related to the one national university? Would Scotchmen submit to have one university for the whole of their country situated in Edinburgh? Has not England revolted against university centralisation in London?

If Trinity College is to be really and truly nationalised something more than its mere "de-sectarianisation" will have to be attempted. 1. A truly national university must be so constituted that, as your correspondent writes, its governing body, professors, fellows, and officials, as at present, are almost universally of one religious persuasion. 2. Irish Roman Catholics and the Presbyterians of Ulster must get a fair share in the governing senate, as well as in other matters pertaining to the administration of the new university. 3. Arrangements will have to be made for the due recognition and adequate representation on the new national university of the various colleges and educational institutions outside Trinity College in the provinces of Ireland. 4. A truly national university must meet the requirements and aspirations not of one sex alone, and hence all its degrees and honours must be open alike to women as to men. (Trinity College, in spite of frequent demands, has not advanced even this length, none of its degrees being open to women.)

Now, Sirs, I have attempted to lay down certain conditions which I think in fairness all will agree must be fulfilled if a university in Ireland is to be a truly national one. May I ask will the authorities of Trinity College allow such modifications of that old and venerated educational institution? And if they refused (as it is certain they would) would any of our political parties in the State for one moment attempt to force them to accept such radical changes in the arrangement and government of their College? As a consequence I am compelled to agree with your conclusion that "the proposal to nationalise Trinity College is therefore as useless as it is impracticable."

I am, Sirs, yours faithfully,

July 2nd, 1900. IRISH GRADUATE.

"LYMPHATIC LEUKÆMIA."

To the Editors of THE LANCET.

SIRS,—I am much indebted to Mr. J. Charlton Briscoe for his courteous criticism of my case. The diagnosis was arrived at not solely from an examination of the blood, but from a careful consideration of all the symptoms. The differential diagnosis between acute Bright's disease, tuberculous peritonitis, ulcerative endocarditis, and other possible causes was carefully discussed. There was no enlargement of the lymphatic glands but the dulness in the left hypochondriac and adjacent regions was probably splenic in origin. Hyperplasia of the lymphatic glands is by no means a constant symptom in lymphocythæmia. Muir states that it may be slight or even absent and Osler expressly mentions that in only four out of his series of 26 cases were the glands enlarged. Enlargement of the glands is much more common in lymphadenoma, a disease of an essentially different character. Leucocytosis is usually met with in the lymphatic form of leucocythæmia, but the number of leucocytes fluctuates greatly from time to time and cases are recorded in which it fell to normal. Although in my case the leucocytes were not absolutely in excess they were relatively so compared with the erythrocytes. The ratio before treatment was 1 in 493, whilst after treatment it fell to 1 in 669. I quite admit that in lymphatic leukæmia a prominent feature is the increase of uninucleated leucocytes, lymphocytes, and slightly larger corpuscles such as are normally present in the blood. In my case the report stated that of the leucocytes 43 per cent. were small cells having a single pale nucleus, but so much doubt evidently existed as to their real nature that the information was of no practical value as an aid to diagnosis. With a patient in a critical condition one cannot afford to suspend treatment whilst experts are discussing the value of methylene blue as a staining agent or considering whether certain appearances are or are not "artefacts." In this case there was some pathological condition of the hæmatopoietic tissues, and whether we choose to label it leukæmia or call it by some similar and perhaps equally indefinite name is a matter of little importance. The essential points are that there was a considerable effusion of fluid into the abdomen, that the patient was sinking rapidly, and that she was restored to safety by the performance by Mr. Walter Spencer of an operation for establishing a collateral circulation.

I am, Sirs, yours faithfully,

Welbeck-street, W., July 2nd, 1900. WILLIAM MURRELL.

To the Editors of THE LANCET.

SIRS,—As Mr. Briscoe's letter in THE LANCET of June 30th with regard to Dr. Murrell's case of "lymphocythæmia" directly concerns myself, I hope you will spare me a short space to reply to that portion which refers to the examination of the blood; any questions as to the clinical diagnosis pass beyond my domain. I think that if Mr. Briscoe will refer to the wording of my reports (and these Dr. Murrell has given *in extenso* and has placed in inverted commas), he will recognise that I was in considerable doubt as to the true nature of the cells which he thinks were possibly lymphocytes. Since reading his letter I have again examined the specimen upon which my first report was founded and find no reason to alter my opinion. I am sure that he will agree that the lymphocyte is the least variable of the leucocytes, and that anyone at all acquainted with blood examinations should make the fewest mistakes when they are the cells under consideration. If I may be excused a little pride, may I express my satisfaction that the arrangements I have made in our clinical laboratory are so soon to bear fruit that will extend beyond our walls? For by our arrangements it is possible to exclude the personal element from a pathological diagnosis entirely. If Mr. Briscoe will favour me with a call at the laboratory he will not only be able to form his own opinion upon the cells in the original blood-film, but also will aid in bringing about that agreement as to the nomenclature of the different varieties of colourless cells found in the blood which is so much needed.

I am, Sirs, yours faithfully,

W. S. LAZARUS-BARLOW.

Clinical Laboratory, Westminster Hospital, July 2nd, 1900.

"THE OPPOSITION OF THE GENERAL MEDICAL COUNCIL WITH RESPECT TO THE MIDWIVES BILL."

To the Editors of THE LANCET.

SIRS,—With reference to the letter of the President of the General Medical Council which appears in THE LANCET of June 30th permit me to inform your readers that the promoters of the Midwives Bill declined to place upon the order paper the amendment to which he calls your attention, or any other amendment which might lay them open to a charge of breach of faith with the General Medical Council.

I am, Sirs, yours faithfully,

F. R. HUMPHREYS,

Honorary Secretary of the Midwives Bill Committee.

Buckingham-street, Strand, W.C., July nd, 1900.

THE OPERATIVE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 23rd Mr. Foster Palmer, urging "early operation in cases of undoubted tubercle of the lung," proclaims that medical treatment of this disease is "vague, empirical, and uncertain," and that surgery alone "offers a really good prospect of success." He argues that when any other organ of the human body is attacked by the tubercle bacillus extirpation is the usual and successful remedy; and straightway he apparently concludes that when the lung becomes tuberculous a similar result must follow a similar operation. It is to be hoped that the future surgery of the lungs will be placed on a far more satisfactory pathological basis. For is it not certain that in almost all cases of adult pulmonary tuberculosis the affection of the lung is secondary to tuberculosis of some other tissue, most frequently to that of the bronchial lymphatic glands? And consequently will not surgical operations on the lung, such as Mr. Palmer describes, prove as useless as if he were to remove the tuberculous index-finger of a patient already suffering from tuberculosis of the wrist-joint?

I am, Sirs, yours faithfully,

Switzerland, June 25th, 1900. CHARLES S. MYERS.

"THE CAUSE OF CARIES OF THE TEETH."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 30th there appeared an annotation on The Cause of Caries of the Teeth in which my theory is characterised as "highly improbable." Yet as far as I am aware there has been *no* case recorded either of rapid and extensive caries of the teeth or of complete freedom from the disease which does not lend support to the theory. The writer says: "That the structure of the tooth plays a most important part in the resistance to caries is within the knowledge of a dental practitioner with even a small experience." This current assumption is repudiated by some of our most acute observers and experienced practitioners (Dr. Black, Mr. Leon Williams, and others). At one time I, too, shared this prevalent belief. When a tooth is soft and non-resistant to an instrument at a part which does not appear to be attacked by caries this condition is usually brought about in the following way. In the mannitic fermentation of sugar the mannite or gum formed clings to the enamel and together with the acids generated in the fermentation gives rise to a general decalcification of the enamel which is not pigmented nor sharply localised and so escapes observation. In the crevices of such teeth

amylaceous and other food particles are apt to lodge. In these situations the caries being further advanced, definitely located, and associated with pigmentation, is easily and distinctly observable.

Perhaps the above explanation may help my critic to reconsider his statement that "the true cause of caries has yet to be discovered and is not quite so simple as Dr. Wallace would lead us to believe." Why not? When the true cause of anything is discovered it generally appears simple. I think, too, it is hardly correct to say that I have "advanced an *ingenious* theory" which is admittedly "so simple." The seriousness and importance of the subject demand that the theory should be put to the test of direct observation rather than be subjected to destructive criticism founded merely on current beliefs.

My critic thinks that "there is something, so far not recognised or understood, which plays a most important part in the liability of teeth to be attacked by caries." If he will only test the theory (as any medical man or dentist can easily do) in a few typical cases of extensive and rapid caries and in a few cases of complete or almost complete freedom from it, I think he will recognise and understand the something which plays that most important part.

I am, Sirs, yours faithfully,

Kingston-on-Thames, July 2nd, 1900. J. SIM WALLACE.

CHELTINE FOODS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 30th you published a letter from which it appears that the makers of these foods now claim that the starch contained in them has been so modified that it is not convertible into diabetic sugar during digestion. Will you permit me to point out that by the action of the amylolytic enzymes of the digestive secretions the poly-saccharids—starch and the dextrins—are not converted into diabetic sugar or dextrose, but into the di-saccharid maltose; so that the claim put forward for the Cheltine foods might equally be made for any amylaceous food. Developing the makers' thesis a stage further one would be led to conclude, in opposition to all experience, that starch is a suitable food for diabetic patients. I am, Sirs, your faithfully,

Cambridge, July 4th, 1900. W. E. DIXON.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Monsoon.—The Unparalleled Extent of the Famine.—Diminished Plague Figures.—The Extermination of Rats by Disease.—Calcium Chloride in Plague Inoculation.—The Standardisation of Haffkine's Prophylactic.—Enteric Fever in the British Army in India.—Rabies.

THE monsoon has reached India and promises a normal amount of rainfall. The conditions are favourable in the west as well as in the east, and anxiety as to the prospects in the famine districts has thus been immensely relieved. Anything like immediate improvement, however, in the numbers under famine relief is hardly to be expected. At the present time there are nearly 6,000,000 persons being aided by charity and the areas affected in the South Punjab, East Sind, Rajputana, Central India, Berar, the Central Provinces, Deccan, Bombay coast districts, Kathiawar, and Gujerat, cover between 600,000 and 700,000 square miles.

The famine of 1876–78 surpassed every previous one in intensity, but the present one is far worse both in severity and extent. The drought of 1899 was unique; not only has the recent drought extended over a wider area, but the tracts affected have been more completely dried up.

With the marked diminution in the plague mortality all interest in and anxiety about it seem to have subsided. For the week ending June 9th only 417 deaths were recorded for the whole of India. Of these Bombay city returned 131 (this is probably much under the correct figures), Karachi 12, Bombay Presidency 57, Calcutta 138, Bengal Presidency 54, and Aden 8. Bombay city continues to return a very high death-rate. It is said that illness of every description abounds, but allowing for a certain amount of cholera, small-pox, and unusual fatality in other diseases the death-rate of over 70 per 1000 and the excess of 547 in the total mortality are too high, and can only be explained by a continuance of the plague epidemic. I am sorry to say that the number of weekly inoculations has much decreased. The heightened birth-rate suggests that the women have not according to custom left the city for their native country. This is probably due to the famine.

Reports from the populous districts in and around Sylhet show that blackwater fever has been assuming the proportions almost of an epidemic. Although it is not so rapid in its fatal effects as plague, very few cases are said to recover. Treatment seems to be of little avail.

The extermination of rats is a difficult work in India owing to the opposition of the natives, so that the experiments recently conducted on the European continent are of especial interest. The object aimed at was the introduction into the rat community of a fatal form of disease which was at the same time harmless to human beings. This has apparently been very successfully accomplished. Into a Paris sewer were introduced 200 healthy rats, and pieces of bread impregnated with the virus of a disease which had previously been proved very fatal to rats were scattered about. Other food was also supplied. In eight days the epidemic broke out and dead bodies were found in considerable numbers. On the twenty-eighth day only eight out of the 200 rats remained alive. The experiment was repeated in Hamburg, Copenhagen, and elsewhere with equally good results. It was found also that even if the poisoned food was laid in open places, such as grain warehouses, either a disappearance of the rats occurred or a great diminution in their number took place. In view of the probable spread of plague by rats it may almost be hoped that this new epidemic will spread all through the rat population in every part of the world. It is by no means certain, however, that rats are the chief means of the dissemination of this disease.

An interesting report on the Haffkine prophylactic has been submitted by Captain Stevenson, I.M.S. Amongst other points he refers to the effect of calcium chloride on the febrile reaction and shows that given both before and after the inoculations it has a good effect. The best results were obtained when the calcium chloride was given a few days before the inoculation as well as after it. Yersin's serum was tried at Mauritius, but the reports were unfavourable.

It is satisfactory to learn that attempts are now being made in the Plague Research Laboratory, Bombay, to standardise Haffkine's prophylactic. Improvements have been effected in the manufacture of the fluid, and since occupying the new premises at Parel no less than 530 brews, or 160,000 doses, have been tested and all were found to be sterile.

The increasing prevalence of enteric fever in India as far as the British army is concerned is shown by the following table:—

Year.	Admissions per 1000 strength.	Year.	Admissions per 1000 strength.
1890	18·5	1895	26·3
1891	20·4	1896	25·5
1892	22·1	1897	32·4
1893	30·1	1898	36·9
1894	20·9		

In spite of every attention to the water-supply and sanitation in the cantonments enteric fever has largely increased. The case death-rate is still very high also, being 24 per cent. It is obvious that the water-supply is not the main or the most important vehicle for the infection. In some places the water is purified, in others it is left untouched, and at some stations there was more fever after purification than before. Boiled water is tasteless and not always cool, and Tommy Atkins will not drink it. The immediate question is not why enteric fever should be prevalent, but why its occurrence has so greatly increased during the past few years. The admission rate for officers in 1898 was no less than 40 per 1000, as against 34 per 1000 in the previous year. This rate is higher than for non-commissioned officers and men, and it shows that the theory of the men contracting enteric fever in the bazaars requires considerable modification.

As the Pasteur Institute at Kasauli is not yet in working order it has been found necessary to send four more soldiers and a child to the Pasteur Institute at Paris.

June 16th.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

Russian Temperance Reform and the Pavilion of the State Monopoly of Alcohol.

AT this moment, when so many international congresses are meeting in Paris to discuss various methods and phases of social reform, there is one exhibit that specially commends itself to those who seek to promote the physical and moral wellbeing of the masses. Throughout the northern half of Europe the prevalence of intemperance is generally considered one of the greatest obstacles to social reform. So great indeed is this evil that it has led to what many would qualify as an exaggerated reaction; one which, for the sake of abolishing that which is unreasonable would also prohibit that which is reasonable, and thus the intemperance of over-indulgence is met by an intemperate desire to enforce total abstinence. But if this be the experience of such countries as Great Britain and the United States of America what must be the state of such a country as Russia? There the vast majority of the population is composed of a simple-minded, good-natured, but totally ignorant peasantry. In their misdt, like a swarm of vampires, there were innumerable dramshop keepers where alcohol insufficiently rectified and of the coarsest description was served out to poor people who had not sufficient knowledge to know that they were drinking what was little better than rank poison. The diseases due to alcoholism were, therefore, widespread, entailing the loss of moral self-control. Clothes, furniture, homesteads, future harvests, implements and cattle, anything and everything that the dram-seller consented to accept as a sufficient pledge was given or signed over for the sake of alcohol. The people were bartering themselves away into a condition of servitude, indeed of slavery, to the dram-seller. Such was the state of ruin induced by alcohol that there were many places where the taxes remained unpaid and no amount of severity on the part of the tax-collectors could extract from the peasantry what they no longer possessed. This financial ruin, of course, also entailed physical and moral degradation. Fortunately the Russian Government, as an autocracy, was better able to deal with the problem than a country where the Government depends on electors who are in a large measure controlled or influenced by public-house keepers, brewers, and distillers. The Russian Government also, and very wisely, deemed that it was its duty to deal with things as they are and not according to the conceptions of some as yet very distant ideal. It had not to decide whether, in the abstract, total abstinence from alcohol was best for the human race, but with the very obvious fact that there are hardly any total abstainers in Russia. Therefore, as people will drink, the practical thing to do is to see that what they drink shall be as free as possible from injurious ingredients. For this purpose a system of inspectorship would have been totally inadequate. The only solution was to create a State monopoly in alcohol. Of course, a great deal has been said against State monopolies, and economists, especially of the older or Manchester school, are loud in their advocacy of the advantages of competition. The problem therefore consisted in effecting a compromise, of retaining some of the advantages of competition in combination with the advantages of a State monopoly. It is the results of this experiment carried out on a gigantic scale which can be studied at the Exhibition in the Pavilion of the Russian Régie of Alcohol situated close to and on the western side of the Eiffel Tower.

M. Gennadi Kartzoff, director of this Pavilion, very courteously placed himself at my disposal and lengthily explained every detail. Indeed, he also remarked that so much had been written in England against Russia that he was especially gratified to find there were English journalists who were willing to study what efforts at reform had been made in his country. It was after the famine of 1891 that the Emperor Alexander III. felt that it was absolutely necessary to attempt a radical reform and in 1894 it was decided to establish a monopoly of alcohol as an experiment. The provinces of Perm, Oufa, Orenburg, and Samara were selected for this purpose. The success was of so decisive a character that the monopoly has been extended to 25 other provinces in the south, south-west, north-west, and in the kingdom of Poland. Perhaps the most remarkable and original feature of the scheme is that private distilleries are not abolished. The State does not monopolise the manufacture of alcohol, it only monopolises the sale of alcohol. Formerly the distiller dealt directly with the dramshop keepers. He had to send out commercial travellers, there were occasional bad debts, and it was difficult to foresee how much alcohol would be sold; in a word, he had to face all the risks common to such undertakings. Now, on the contrary, the Government informs the distiller how much alcohol will be required during the forthcoming year. The distiller is certain to be paid for the same; he has not to deal with a multitude of more or less doubtful customers and he escapes from the risk of producing too much or too little. On the other hand, he still competes with other distillers so as to secure large orders from the one customer, the State. Most of the alcohol bought by the State is the raw unrectified product of distillation. A very ingenious sealed meter is provided by the State for the use of distillers. A large float in the cylinder which receives the liquid indicates and registers its alcoholic strength. From this cylinder the alcohol flows into a drum which revolves and empties itself when weighed down by the filling of one of its partitions. Thus quantity and strength are automatically registered. The alcohol is then conveyed from the private distillery to the State depôt, where it is analysed by the Savalle test, with sulphuric acid for amylic alcohol and with fuchsinosulphuric for aldehydes or with aniline for furfurol and with permanganate of potassium to determine its degree of oxidation. The whole of this process is shown at the Pavilion which, on a reduced scale, is the exact reproduction of a Russian State depôt for receiving, rectifying, and for the sale of, alcohol. The water, also, used for diluting the alcohol, is analysed, and according to the result of this analysis is treated chemically or distilled so that the water shall be uniform in its composition and purity. In all cases the water is absolutely sterilised.

A great point is made of the fact that whatever may be done with the alcohol it is never touched by the human hand and one source of contamination is thus done away with. The pipes and the soldering of the pipes that serve to convey the alcohol from vat to vat or from filter to filter are exhibited, and the attention of the visitor is drawn to this important consideration. By a syphon arrangement and an air-pump the alcohol is raised from the ground floor to the second floor, from thence by gravitation it can flow through the filters, &c. There is a special apparatus with an electric motor to ensure the satisfactory mixing of the alcohol with water, and it is then kept in a reservoir till the time comes for transforming it into brandy. The brandy is then raised into a cylinder where pressure is brought to bear so that it can pass first through four charcoal filters. Then so as to remove any particles of charcoal it is passed through two sand filters. As this process causes some slight loss of alcoholic strength the liquid, now perfectly clear, is collected in another vat where it is brought up to its normal strength, generally 40 degrees. All this is done mechanically, and so also is the bottling which now ensues. The dirty bottles are placed on a wheel the lower portion of which is submerged in a vat of water. The weight of the bottles as they are placed on one side of this wheel causes it to revolve, bringing up on the opposite side of the wheel the bottles that have been some time in the water. With the aid of a brush the labels are then easily removed. The bottle is then stood neck downwards over an upright pipe. By pushing a handle at the side of the table in one direction water is squirted inside the bottle; by pushing the handle in the opposite direction the water and sand are violently discharged. If this does not suffice the bottle can be affixed to a revolving brush which removes any hard substance adhering inside. Then there is a table with a little measured reservoir above. Eight rubber tubes are introduced in the necks of eight bottles. On turning a handle to the right the four bottles on that side receive the exact amount of brandy they should contain, and while the handle is turned to the left to fill the bottles on that side the first four are removed and empty ones are put in their place. The bottle is then placed under the corking machine. By pressing a lever, not only is the cork forced into the bottle, but a little piece of vegetable parchment is brought under the cork, which it surrounds and covers, preventing any contact between the cork and the alcohol. Thus the cork does not decompose in the bottle and cannot spoil the brandy. This is also important from an antiseptic point of view, as it is difficult to guarantee that the corks are aseptic. Dr.

Roux of the Pasteur Institute was much impressed by this contrivance and said it was the best thing of the sort he had seen. In the corking of the bottles, as in every other detail, everything is, as already stated, done by machinery, the alcohol is never in contact with anything that has been touched by the hands of the workers.

Finally, there is an exact reproduction of a Russian depôt for the retail sale of brandy, or *vodki* as it is called. It consists of a counter well protected with strong wire so that no one can reach over towards the bottles which are on shelves behind. In front there is only a little standing room for the customers, there are no glasses, and no one is allowed to drink on the premises. The attendants are employed by the Government, they receive fixed salaries, they are in no wise interested in pushing the sale, and they are forbidden to give credit. One of the great objects was to abolish the village taverns or dramshops which have been the ruin of so many peasants. On the other hand, the utility of the tavern as a place of social intercourse could not be denied, consequently out of the profits made by the monopoly of the sale of alcohol no less than 826,000 subsidies, amounting to 1,500.000 roubles, were granted to temperance committees in 1897. The mission of these committees is to create establishments where all the advantages of social intercourse can be enjoyed without the necessity of drinking alcohol. Therefore they establish cheap restaurants, reading-rooms, libraries, and halls for popular lectures, concerts, &c., and this they are now able to do out of the profits from the sale of alcoholic liquors. But though the low-class taprooms or public-houses have been abolished still inns and restaurants are necessary. Therefore the retailing of alcohol to be drunk on the premises is sanctioned at railway stations, in hotels, high-road inns, and such places, but this is done in such a manner that innkeepers have no interest in pushing the sale of alcohol. They only receive a commission of 10 per cent. on the *vodki* they sell. If a higher commission is given it is because they have a long way to go to the nearest State depôt. But it will be said that the innkeepers could refill the bottles with some spurious alcohol brought from an illicit distillery. To meet this, the sale of *vodki* on draught is absolutely prohibited. Every purchaser must have an entire bottle, so bottles that only hold enough for one drink are provided. These contain six centilitres of *vodki*, and the retail price in Russia of these bottles is equal to about seven farthings of English money. On the bottle a label indicates the quantity and the alcoholic strength of the *vodki*. The cork is sealed with the Imperial arms. The price at which it is to be retailed is also stated so that the innkeepers cannot in any way increase the profit he is to make. Apart also from these printed statements the colour of the wax indicates the strength and value of the contents of the bottle. Deception is not practicable and if it were practicable the penalty is 15 years in Siberia. The State takes back the empty bottles if they retain their labels and the number of the factory. The State alone has the right to fill the bottles and the Imperial seal is the guarantee of the purity of their contents. As the profit on the sale of alcohol is only about 10 per cent. no one is particularly interested in pushing the trade, and therefore there is no attempt to increase the demand. Also it is strictly a ready-money trade, so that drunkards cannot get into debt with the publican. Nevertheless, but for the small bottles some form of fraud might still be possible. If a publican can draw the cork from a bottle and pour out only a part of its contents there is no knowing with what he may refill the bottle. The Russian innkeeper, however, must serve an entire bottle to his customer; the consumer alone has the right to break the seal, and to serve a bottle with a broken seal is a penal offence. This rule can be easily observed, as there are bottles small enough to contain sufficient for one drink only.

The results of this great reform have been beneficent, financially and morally. The State sells a litre of alcohol for 3 francs 92 centimes. The cost of production, including excise duty, indemnities to towns which by the abolishing of the licensing system have lost a source of income, &c., amounts to 3·26 centimes. No indemnity whatsoever was paid to the dramshop keepers. Many of them were very rich and in any case had done harm enough to debar themselves from any claim for compensation. In 1897 the 66 centimes of net profit per litre of alcohol brought in a revenue of 47,000,000 francs. But what is even more advantageous, districts that were ten years in arrears in the payment of direct taxation are now clear and are paying regularly all their taxes. The Emperor Alexander III. in discussing this scheme had said that any reduction of indirect revenue due to the taxing of alcohol would be compensated by an increase in direct taxation arising from the greater prosperity of the people. This anticipation has been realised. Drunkenness has been very greatly reduced, there are less crime and debauchery, and there is a consequent distinct improvement in public health. The deposits made in the savings-banks have increased in a marked manner, and this improvement would have been even more emphatic but for the very serious famines that have prevailed in different parts of Russia.

To sum up, the position stands thus. The retailer makes less profit out of the sale of alcohol than he does out of anything else which he may have to sell; therefore he is not at all desirous to induce his customers to drink, he would much prefer to sell them food, coffee, or tea. Then as the alcohol is absolutely pure it is not so injurious to the consumer. As all the low-class dramshops are abolished the peasantry are no longer induced to run into debt for the sake of drink; but, on the other hand, the temperance committees receive funds from the State which enable them to provide rational enjoyment for the peasantry. The results are a notable decrease in drunkenness and crime and a corresponding increase in public revenue by the more regular payment of direct taxation and in private prosperity, as indicated by the increase of deposits made in the savings-banks.

Now, without going all the way to Russia to study the details, technical processes, administrative complications, &c., of this great and radical reform, the entire subject can be thoroughly investigated here in Paris and within a few yards of the Eiffel Tower. This, indeed, is a unique opportunity. All those who devote so much time to studying and discussing the great question of temperance reform, the prevention of the diseases due to alcoholism, &c., have now within easy reach a practical, complete, technical, and general example and illustration of one of the boldest, the most far-reaching and systematic efforts that any modern European Government has ever ventured to make when seeking to grapple with this terrible and menacing problem.

Paris, July 1st.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague at Sydney for the week ending May 19th are as follows: remaining at the beginning of the week, 86; admitted, 23; discharged, 0; died, nine; remaining at the end of the week, 100. The totals up to the end of the week are as follows: cases, 239; deaths, 82; recovered, 57; "contacts," 1351; "contacts" remaining, 140; cases among "contacts," seven.

The second series of inoculations, begun last week, proceeds slowly though steadily. An average number for each of the past nine days is 200. No excitement and comparatively little interest in it are manifested. Two factors, however, have to be considered besides the great abatement in the panic with which the public were stricken at the date of the former inoculations. The present series has been carefully organised and steps have been taken to secure inoculation of the remaining workers in, and inhabitants of, the first infected area, a considerable proportion of whom were inoculated on the earlier occasion. Candidates now have to apply for tickets, which are dated for some day later than that of application, and they must present themselves on that day or procure a fresh ticket. Business firms may make application for their employés by letter and receive by post tickets dated for different days, so as not unduly to interrupt business. Government departments may follow the same course or, if they choose to provide themselves with a medical man, may be supplied with enough prophylactic to inoculate all of the staff who desire it. Tickets are allocated to days in limited numbers; half of the number are distributed by post as just mentioned, the other half are reserved for applicants in person. Tickets are distributed to persons and by post every morning; inoculations are performed every afternoon. Two afternoons a week are reserved for women and children. The city townhall furnishes a place; the staff consists of two medical men, two preparators (medical students), and two clerks.

The number of persons in whom plague has developed after inoculation has been 11. One was attacked on the day of inoculation, one each on the first, second, and third days therefrom, three on the fourth day, and one each on the fifth, seventh, fourteenth, and thirty-second days. All of these recovered, and most of them had conspicuously light attacks. One other patient who died said that he had been inoculated, but his name did not appear in the lists; his family knew nothing of it, but a fellow clerk said that he thought he had been inoculated, because though he never told him so directly, he had expressed an intention of submitting himself, did take leave one afternoon, and for two or three days thereafter complained of his arm. The informant seemed certain that he had been inoculated. No reason for this secrecy coming to light, it seemed possible that he gave a false name to the registering clerk.

Of the total deaths mentioned above 27 have occurred before removal to isolation; eight occurred at one or other of the general hospitals where their cases were identified, though they had either already died before official inspection or were too ill for removal; and 19 died at their residences. Sometimes the cause of death in these cases was uncertified and the cases were brought to notice by a coroner; sometimes the patient was seen alive by a member of the medical staff but died soon afterwards; sometimes very acute cases were reported by medical men but died before they could be examined; and occasionally the unexpected occurrence of death first gave the medical attendant reason to think of plague and caused him to refer the case to the medical staff. In five of the 27 cases the date of attack could not be ascertained; the remainder died on days after attack from the first to the eighth as follows: 1, 3, 7, 3, 2, 2, 2, 2. In all cases of predecease the diagnosis was made by post-mortem and bacteriological examination.

Chinese have now been attacked in eight instances; seven of the patients have died. The dates of discovery were April 9th, 16th, 23rd, and 26th, and May 8th, 9th, 15th, and 17th. Possibly the latter dates offer a hint of tendency in the disease to take hold of these Asiatics. At all events, special search-parties have been organised by the Department of Public Health and next week they will go through the three small Chinese quarters which exist in Sydney. In all the cases there is strong reason to believe that the patient had been removed from some better or more populous residence to the unimportant place in which he was found. In one such case the sufferer was found in a room attached to a mission chapel where no one lived; another patient asserted that he had been tramping over the country in search of work and had arrived in Sydney by train from a remote station the day he fell ill and was discovered—a story which his appearance belied and which was easily shown to be false by the police and by the guards of the only trains by which he could have travelled. Especial care was taken to procure substantial evidence of the facts, although it is apparent that a tramp could not have acquired plague in the bush under existing conditions.

Two litres of Yersin-Roux serum arrived in bottles holding 20 cubic centimetres each and the use of it was commenced at the end of last week. The results could not be mentioned in sufficient detail in this communication, were they complete; they seem, however, to bid fair to be satisfactory, and it may be noted that all patients thus far treated have a pulse of much greater strength than is usual at the corresponding date of illness in untreated cases be they mild or severe. From this it may be inferred that the serum is an efficient antitoxin at least.

May 21st.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University of Birmingham.

HER MAJESTY in pursuance of the provisions of the Charter of the new university has been pleased to appoint Oliver J. Lodge, D.Sc., LL.D., F.R.S., Professor of Experimental Physics in the University College, Liverpool, to be Principal of the University of Birmingham. This appointment has given general satisfaction to all interested in the university. Dr. Lodge's reputation is a wide and substantial one. His work on electricity and light and his researches in the field of experimental physics and allied subjects have made his name familiar and popular as a writer and teacher of the first order. Having just completed his forty-ninth year Dr. Lodge may look forward to his reign in this new sphere with hopefulness and confidence, while his colleagues will rest assured that they will have the association of an eminent and active director in all questions affecting the progress and distinction of the University. In illustration of the activity of the students at present engaged at Mason College a meeting was held on June 12th for the purpose of forming a University company of Volunteers. The Dean of the Medical Faculty—Dr. B. C. A. Windle—presided and much enthusiasm was exhibited. The object is to get a sufficient number of drills completed before August 6th and then to appear as a complete company on Salisbury Plain.

A New Asylum.

An inquiry under the auspices of the Local Government Board was held on June 21st for the purpose of borrowing £249,250 for the building a new asylum at Hollymoor. The Town Clerk explained the objects of the inquiry and gave details of the necessity and the approximate cost. He stated that the authorised accommodation for patients at the existing asylums of Winson Green, and at Rubery Hill was for 1429, but as the members had been for some time increasing this was found to be insufficient. Thus the number of patients in the two asylums in 1891 was 1205, in 1900, 1528. The increase was stated to be normal in proportion to the increase of population, amounting to about 40 per annum. To meet the increase temporary provisions were made in 1897 by a lease of Sandwell Hall at a rental of £300 per annum, giving accommodation for 150 male patients. Another building had also been provided for a time to meet the difficulties of the increase which would be for female patients. It was pointed out that all these additional premises were held on limited leases only and that the necessity of permanent buildings was obvious from the statistics adduced. The expense will be a heavy tax upon the ratepayers, for though the Government, recognising that lunacy is a national and not a local misfortune, contribute towards the maintenance of the inmates the cost of the new buildings must be borne by local taxation; fortunately this extends over a series of years.

Inebriate Homes.

Corngreaves Hall, near Birmingham, was the scene of an animated gathering on June 13th, when it was formally opened as an inebriate home for women. The building has been acquired by the Worcester Diocesan Church of England Temperance Society. It is intended for the reception of inebriate women of any denomination, the age-limit being from 20 to 45 years. No person will be admitted for less than 12 months and patients are strongly advised to enter for two years. Accommodation is provided for 30 patients and arrangements are made for three grades, payment being accordingly. Employment and recreation will be duly provided. Under the present able administration the results are looked forward to with cheerfulness and hope. The board has appointed two representatives from Birmingham on the management, taken from the justices of the city roll.

Hospital Saturday.

The sum paid into the bank for this year's contributions amounts to £16,111, as compared with £16,521 last year. This falls short of the £20,000 asked for, but under existing circumstances it must be regarded as a valuable contribution.

July 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

A New Hospital in Liverpool for the Treatment of Tropical Diseases.

IT is proposed to erect a new hospital in Liverpool for the special treatment of tropical diseases, as the accommodation provided in the Thompson-Yates Ward at the Royal Southern Hospital has become too limited for the number of cases applying for treatment. At the banquet at the Adelphi

Hotel on June 25th in honour of Dr. H. E. Durham and Dr. Walter Myers, on the eve of their departure for the Amazon, subscriptions amounting to about £2500 were announced towards that object. It was certainly a happy thought which suggested to Mr. Alfred L. Jones, who presided, the association of the name of Miss Mary Kingsley, the intrepid traveller and friend of the negro, with the new hospital. No more fitting memorial to perpetuate that lady's name can be conceived than that of connecting her name with an undertaking which is intended to benefit the lands she loved so well.

The Thompson-Yates Laboratory Reports.

The first issue of the Thompson-Yates' Laboratory Reports, vols. i. and ii., 1900, has just appeared from the University Press of Liverpool. The reports consist of two large quarto volumes, handsomely designed and furnished with numerous coloured plates and illustrations. The first volume, which consists of 238 pages, contains the account of the opening of the laboratories in October, 1898, by Lord Lister, P.R.S., who was accompanied on that occasion by Professor Virchow and a distinguished gathering of scientific and representative men. An address delivered before the medical students of University College, Liverpool, by the donor of the laboratories, the Rev. S. A. Thompson-Yates, will also be found in the first volume. In the second volume, which contains 265 pages, reports are given of the various departments, including the report of the first malarial expedition to West Africa by Major R. Ross, I.M.S., Dr. H. E. Annett, and Mr. E. E. Austen, which clearly indicate the many ways in which the University teaching in the schools of physiology and pathology is directly applicable to the needs of the community, including the wide sphere of our colonies, both as regards the prevention and cure of disease at home and abroad and the advancement of commerce. They are intended to promote learning and record research in the various branches of physiology and pathology, and thus to carry out the wishes of the founders of the two schools. They also contain reprints from various authors and medical journals. The editors are Professor Rubert Boyce and Professor C. S. Sherrington, both of University College, Liverpool, assisted by junior members of the staff of the schools of pathology and physiology.

July 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chair of Systematic Medicine in the University of Glasgow.

THE Chair of Systematic Medicine in the University of Glasgow, vacant by the resignation of Sir William Gairdner, has been filled by Her Majesty the Queen having been pleased to appoint, upon the recommendation of the Secretary for Scotland, Professor McCall Anderson, the Professor of Clinical Medicine in the University. Dr. McCall Anderson is M.D. of the University, and F.F.P.S. of Glasgow. He is physician to the Glasgow Western Infirmary and consulting physician to sundry other Glasgow medical institutions. He is the author of various medical works, chiefly dealing with diseases of the skin.

The Forthcoming Health Congress in Aberdeen.

The Public Health Congress, at which 716 delegates have now promised to be present, to be held at Aberdeen under the auspices of the Royal Institute of Public Health, will extend from Thursday, August 2nd, to Tuesday, August 7th. It is intended to open the proceedings with an address by the President, the Earl of Aberdeen, in the Mitchell Hall, Marischal College, and it is expected that the delegates will be entertained by the corporation at a reception and a luncheon. Saturday will be devoted to excursions to Balmoral, &c. On Sunday the Congress as a body will attend service in the West Parish Church to be conducted by Principal Marshall Lang, Aberdeen University. Three special papers will be read to all the members—viz., one on "Disinfection" by Professor Delépine of Owens College, Manchester; one on "Sewage" by Professor Percy Frankland, F.R.S., Birmingham; and one on "The Origin and Treatment of Malarial Fever," by Dr. Patrick Manson, medical adviser to the Colonial Office. Numerous papers have also been promised for the sectional meetings, including one on "Fever Hospital Construction," by the city architect of Edinburgh; one on "Modern Workshops," by Miss Paterson, H.M. Inspector of Factories; and several on the housing of the working classes, meat inspection, ambulance work, vaccination, infant mortality, notification of measles, &c. There will also be submitted and discussed a report on the inquiry made into the chemical and bacteriological condition of the air in the London Board Schools.

Illness of Professor Ogston.

Much regret is felt in Aberdeen at the fact of Professor Alexander Ogston being "down" with fever at Bloemfontein Hospital. It is not yet known whether the fever is enteric, but Professor Ogston was no doubt exposed more to infection than other acting army surgeons as he was not attached to any particular hospital but took a general survey of the medical arrangements at the seat of war in South Africa.

July 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE Council of the Royal College of Surgeons in Ireland have by a circular letter to the Fellows dated June 25th called attention to a resolution which was adopted at the annual meeting of the College held on June 2nd. The resolution stated—

That in the opinion of this meeting of the College the practice of canvassing for the offices of President, Vice-President, or Members of Council should cease.

That it be a direction to the Council to ascertain by means of a circular sent to each of the Fellows whether they would wish, with the object of discouraging canvassing, that the Council should immediately after an election to the office of President or Vice-President recommend to the College the name of one Fellow for election to the next ensuing vacancy in each of these chairs.

For the purpose of carrying out the direction contained in the above resolution a short voting-paper has just been sent to each of the Fellows so that he may state his opinion—for or against—the method suggested in the resolution of preventing canvassing for the Presidency and Vice-Presidency of the College. The method adopted by the general meeting of obtaining the opinion of the College as to canvassing is obviously open to two objections. It does not include any provision to prevent canvassing for the Membership of the Council, and secondly, it gives no opportunity to a Fellow who is opposed to canvassing but dislikes the proposed means for preventing it to give an expression to his views.

New Medical Deputy Lieutenant.

The *Dublin Gazette* announces the appointment as Deputy Lieutenant of the City and County of Londonderry of Joseph Byrne, F.R.C.S.Irel., of Londonderry, his commission bearing date June 13th, 1900.

The Belfast Workhouse.

At the usual meeting of the Belfast Board of Guardians on June 19th a letter was read from the Local Government Board, based on a sworn inquiry, held by one of their inspectors, Mr. Robert Agnew, which certainly is a terrible indictment of the management of that extraordinary place. The letter states that it has been amply proved that, as regards the expenditure of such a large amount as £8367 upon buildings, repairs, and fittings in connexion with the Belfast Union Workhouse between August, 1897, and December, 1899, the general regulations (such as that any work or repairs to be executed in the workhouse exceeding the cost of £20 in one sum shall be contracted for by the guardians according to rules laid down) have been to a great degree ignored or evaded and broken. Upon a careful consideration of the evidence and after a close examination of the procedure adopted in making payments, it appears clear to the Local Government Board that a system was followed so as to make it appear that the law and regulations were being adhered to, while, as a matter of fact, they were being systematically broken. So impressed are the Local Government Board with the serious condition of affairs that they have decided to dismiss the master, but they will withhold the sealed order to this effect for a week in order to give him an opportunity of resigning his position immediately. (This he has now done, submitting a medical certificate to

the effect that he was physically unable to grapple with the duties of his office.) The Local Government Board also regard the conduct of two other minor officials with extreme disapproval. It need hardly be said that this extraordinarily severe censure of the Belfast Workhouse by the Local Government Board has produced a very marked effect on the general public who have now lost all confidence in the management of the Belfast Workhouse, and this feeling of public dissatisfaction has been deepened by the guardians in the coolest possible way approving of an expenditure of £13,500 for the purpose of providing a new board-room and clerks' offices in the workhouse. It is hoped that the Local Government Board will stop this most useless expenditure. Again, it is stated in the press that another scheme is being put forward by the guardians for the erection of new school buildings for the workhouse children on a site at the foot of Mount Divis, outside the present workhouse altogether, and it is presumed these may cost £100,000, while the present school buildings inside the workhouse would cost £25,000. Fortunately, without a new Act of Parliament such extravagance cannot be perpetrated. The Local Government Board say that the management of the Belfast Workhouse has been characterised by "gross irregularities" and "gross carelessness," and that there is inefficient supervision by responsible officials; but can the guardians themselves be acquitted of all blame for the lamentable state of a great public institution? One of the leading Belfast morning newspapers says: "It is the chattering incompetence of many of the guardians themselves that has long made the board the scandal and disgrace of Belfast, and we hope the ratepayers will take due note of what is going on and will vigorously apply the policy of the 'sweeping brush' at the next election."

Royal University Graduates' Association.

The first annual meeting of the Royal University Graduates' Association (the objects of which were stated in THE LANCET of June 16th, p. 1760) was held in Belfast on June 25th, the President, Dr. W. A. McKeown, occupying the chair. In their report the council state that the association has received the support of a large number of the graduates of the University, all the faculties being well represented, but they regret to find that so many have neglected to register as members of Convocation. Some improvement has been made in the University examinations, and the question of the appointment of extern examiners (so strongly advocated by the association) is now under the consideration of the Senate. Financially there is a balance in the treasurer's hands. The President, in moving the adoption of the report, said the action of the association had been directed by the principle that university education should not be under clerical control. The election of Dr. Walton Browne by the graduates to a place on the Senate of the Royal University had helped to secure a measure of fair play to the students of provincial schools and some improvement in the conduct of the examinations. He said many graduates had not joined the association because of the fundamental rule, not only pledging opposition to sectarian universities, but to provincial universities. It had been said why should the great medical school of Belfast be kept in leading-strings to Dublin? He (Dr. McKeown) sympathised with that argument and no one disliked more thoroughly the Dublin influence or was more desirous to reduce it to its legitimate proportions than himself, and in any reorganisation of the University it was a plank of their platform that if institutions were to be represented on the examining boards that representation must be regulated according to the importance of the respective institutions as estimated by the average number of graduate students for a period of years. The objection of the association to sectarian universities was on principle and admitted of no compromise, while that to a provincial university was a matter of experience and might alter with time and circumstance. For example, if the numbers of university students largely increased in Belfast, if funds were available for a university on so liberal a scale as to secure and hold the very best teachers and put the university above the temptation of increasing its students by lowering the standard, then he (Dr. McKeown) would be the very last person to oppose, but on the contrary, would strongly advocate the establishment of a local university, provided that in its organisation there was not even an appearance of sectarianism. Dr. McKeown then gave a very interesting address on Irish University education, in which he opposed very strongly Mr. Balfour's proposed settlement and again brought forward his own plan of local government for the Queen's Colleges with separation from State connexion and a reorganisation of the Royal University as a means of settling the question. Resolutions having been passed against the establishment of State-endowed sectarian universities, deprecating the destruction of the Royal University, advocating the appointment of extern examiners, and expressing satisfaction that the papers issued by the Foreign and Colonial Offices showed that there was no precedent in foreign countries or in the Colonies for the establishment of sectarian universities (on Mr. Balfour's lines), the office-bearers for the ensuing year were appointed. At the request of the meeting Dr. McKeown's interesting presidential address is to be printed.

July 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Right of Property in Medical Records.

AT a recent meeting of the Society of Legal Medicine M. Brouardel brought forward a most interesting point in reference to a matter upon which he had been consulted. A medical man died and his only son, also a medical man, entered into possession of his late father's house and carried on the practice. He was anxious to consult certain notes and observations accumulated by his father which were stored away in the consulting room. But his step-mother (*belle-mère*) as co-heiress refused to let the son make use of the notes, ostensibly on the plea that she was anxious to avoid any violation of professional secrecy. M. Brouardel was of opinion that there would be no violation of secrecy, but simply a continuation of the trust from the first medical man to the second who succeeded and who would take over the medical observations collected by his predecessor. A legal expert, however—namely, M. Danet—held a different opinion and thought that all the notes and case-books should be burned. In face of this difference of opinion the question should be left to the courts to decide. In the course of the discussion at the Society of Legal Medicine M. Ladreit de la Charrière gave it as his opinion that a man who sells his practice has no right to communicate details as to the past medical history of his clients because they may choose to go to some other medical man than the purchaser of the practice. M. Rocher said that French law did not recognise the sale of practices. *A fortiori* then a medical man had no right to hand over to his successor details of patients without their consent. He agreed with M. Danet that the documents should be burned. M. Brouardel protested against this view, for if whenever a practitioner died all his notes were to be destroyed great injury would be done to the patients themselves and science would be deprived of a very valuable mine of collected knowledge. The matter was in the end remitted to a special committee, on the motion of M. Brouardel.

Prophylaxis of Typhoid Fever in Paris.

The Council of Hygiene and Public Health have unanimously passed the following rules which were formulated by M. Roy des Barres in his report upon typhoid fever in Paris during 1899 and the early months of 1900. 1. Steps shall be taken to ensure the formation of a sufficient protection zone round the gathering-grounds of spring waters. 2. The head waters are to be strictly examined so as to eliminate as far as possible any source of infection. 3. Throughout their course these waters shall be kept covered in. 4. The necessity for a final purification of the water shall be kept in mind whether this be done by filtration or some other process, such as using ozone, and experiments as to the best means for sterilisation in bulk shall be set on foot. 5. Filtered river water and spring water shall not be mixed as a rule, but if at any time such admixture shall become necessary means shall be taken for clearly setting forth the details of the admixture and the probable length of time for which such mixed supply shall last. 6. Every district supplied shall be informed as soon as there shall be any change made in the source of supply. In addition, the Council of Hygiene and Public Health of the Department of the Seine have passed a resolution to the effect that the administration shall as soon as possible supply with drinking water the public

parks and gardens, together with the restaurants contained therein. Fountains and conduits are to be specially labeled so that it can be seen at once which supply drinking water and which supply water for cleansing or gardening purposes only. The Prefect of the Seine has accordingly ordered that enamelled plaques bearing the words "drinking water" or "river water" shall be immediately affixed to all the fountains in the parks and squares.

The Action of Artificial Abscess in Experimentally Produced Anthrax.

M. Fochier and M. Mérieux of Lyons communicated to the Society of Biology at a meeting held on June 23rd the results of some experiments which they had made as to the effect of an artificially produced abscess in the case of animals inoculated with anthrax. If a rabbit is simultaneously inoculated with a virulent anthrax culture and with essence of turpentine in a dose of 0·25 of a cubic centimetre it either survives altogether or takes a much longer time to die than a control animal which dies at the end of a period lasting on an average for about 66 hours. The results of the turpentine injection are, as a rule, in harmony with the inflammatory reaction which it produces. If given 24 hours before the anthrax culture it produces far less marked effects than if given simultaneously. Given some hours after the anthrax culture its effects varied much. Intra-muscular injection gave less good results than subcutaneous injection. When the animals which survived were killed and examined they showed no signs, either macroscopically or bacteriologically, of anthrax. If a surviving animal was again inoculated it succumbed with undoubted signs of anthrax although the symptoms were less marked than in an ordinary animal. If the turpentine were injected into the dorsal region and the anthrax into the abdominal region M. Fochier and M. Mérieux noticed that there appeared, close to the œdema produced by the anthrax culture, another zone of gelatinous œdema which was apparently a sign of defensive action on the part of the organism. Also in animals thus treated the anthrax œdema sometimes did not appear or, at any rate, was less marked than in a control animal, and in those animals that died very few bacilli were found in the spleen and in some instances cultures made from them remained sterile. The artificial abscess, when it burst spontaneously, either did not become infected or, if it did, hæmorrhagic ulcerations were produced which without doubt contributed towards the death of the animal.

Laboratory Work of the Board of Health of Ontario for 1899.

THE provincial bacteriologist, Dr. J. J. Mackenzie, gives the results of his past year's work in the annual report of the board, which has but recently been handed to the profession. During the year the total number of specimens examined in the laboratory amounted to 1370, made up as follows: suspected sputum, 629; suspected exudate, 375; suspected typhoid blood, 164; waters for bacteriological examination, 16; waters for chemical examination, 29; miscellaneous samples, 52; and suspected rabies, 5. Out of something like 2400 physicians in the province of Ontario alone 300 physicians sent in 1100 of these specimens. The report shows as regards the examinations for suspected tuberculosis that 32 cases were diagnosed positively within two months of the presumed date of onset of the disease. From this is emphasised the importance of an early examination of the sputum, especially so when one remembers the success by modern methods which follows early diagnosis. As to the 375 diphtheria swabs, 147 of these gave positive cultures. The advantages of the early administration of antitoxin are also dwelt upon. There were four cases of suspected cerebro-spinal meningitis, only one of which showed the diplococcus intracellularis meningitidis, which was a fatal case with an illness of 48 hours. Among the miscellaneous investigations of the laboratory was a study of the character of a bacillus found in grass which resembles the tubercle bacillus. It is pointed out in the report that the occurrence of this bacillus in butter has undoubtedly given rise to error, as it is apt to be reported as the bacillus of tuberculosis. Its growth in culture media differs, however, from that of the bacillus of tuberculosis as it is more luxuriant and rapid. This organism was found in several specimens of hay, and from one the bacteriologist was successful in isolating it in pure culture. It was also demonstrated in the resulting cultures that the form was identical with Rabinowitch's butter bacillus; and experiments on animals showed it to have a very slight degree of virulence. Dr. Mackenzie was further able to show that its peculiar staining characters are due, as in the bacillus of tuberculosis, to a fatty envelope, but found that, contrary to what occurs in the bacillus of tuberculosis, this fatty envelope can be readily dissolved off with alcohol, so that after boiling in alcohol for ten minutes the organism no longer takes the peculiar stain but stains like any other form.

Alum Baking Powders.

From the Department of Inland Revenue at the capital, Ottawa, has just been issued a bulletin of some 39 pages which gives the results of the work of the Dominion chemists for some time past. No similar bulletin has been issued from the department on the same subject since 1880. It contains the details of the analysis of 156 samples of these powders purchased throughout the Dominion; and of this number only 44 samples are entirely free from alum. That is to say, over 70 per cent. of the baking powders sold and used in this country contain alum. A very large part of the bulletin is taken up with a study of the scientific evidence bearing upon the physiological effects of alum, especially that evidence which has accumulated since 1880. The conclusions reached are very outspoken and decided so far as alum itself is concerned. Whilst many manufacturers and some chemists claim that in a well-made alum powder no alum as such remains in the bread, but hydrate and phosphate of alumina, still the characters of these products have also been carefully and thoroughly gone into and the following conclusions arrived at: "The question of the harmlessness of hydrate of alumina has, however, not been proven, and the most that can be said for it is that the case is still unsettled. The health of a nation is too serious a matter to be imperilled lightly and if it be impossible to secure prohibitory legislation against alum baking powders it is all the more desirable that manufacturers of these powders should be required to state their composition on the package, so that consumers may know what they buy and use. Until it is demonstrated that hydrate of alumina is harmless in food the use of alum baking powders is attended with a very serious risk; while not even the proving of these substances harmless would establish the safety of these powders, since, for reasons already mentioned, it is quite uncertain that the reaction is completed in the bread."

Special Hospital Accommodation for Inebriates.

For some years past an effort has been put forth by leading members of the profession in Ontario, assisted by prominent lay gentlemen, to bring the Ontario Government to a sense of their duty in providing accommodation for the special treatment of those unfortunates addicted to the liquor habit. Their labours are apparently in the immediate future to be crowned with success. At the last session of the local legislature an influential delegation waited on the Premier of the province, the Hon. Dr. G. W. Ross, with the result that a Bill has been drafted for introduction into the House in the next session. This Bill will provide for the immediate appointment of a superintendent, a medical man who has devoted some attention to the treatment of the chronic inebriate. He will at once proceed to organise cottage hospitals throughout the province or to see that special wards are set apart in the general hospitals already existing for the proper care and treatment of these patients. The legislation will further provide that in towns of 20,000 and over special commissioners shall be appointed to look after this work, whose duty will be to induce inebriates to undergo treatment and to visit and encourage them while they are undergoing treatment. Steps will also have to be taken to make provision for their employment and to endeavour to change their environment and to place them on a higher plane of life and living. The Government will also be asked to make a per diem grant in addition to the regular hospital grant. The scheme has been approved of by practically all the leading medical societies throughout the country.

Another Anti-vivisection Bill in the United States.

IN THE LANCET of Feb. 24th (p. 583) I referred to the Anti-vivisection Bill introduced by Senator Gallinger in the district of Columbia, having for its nominal object the prevention of cruelty to animals. Owing to the opposition against this Bill of the most prominent scientific and medical men in the country, including Dr. Osler, Professor Welch, Professor Bowditch, Professor Eliot, and Dr. Keen (President of the American Medical Association), Senator Gallinger was induced to hold a meeting at which both sides of the question might be fairly placed before the public and the whole matter discussed at length. This meeting was held on Feb. 21st at Washington and, as may be imagined, was both instructive and interesting. The case for the vivisectionists was presented in the most convincing manner by Dr. Hare, Dr. Keen, Professor Welch, and Professor Bowditch. Dr. Welch's arguments were especially to the point. He contended that there was no necessity whatever for further legislation in regard to vivisection as the existing law permits only "properly" conducted scientific experiments or investigations, which experiments are to be performed only under the authority of the faculty of some regularly incorporated medical college, university, or scientific society. He also drew attention to perhaps the most serious fault of the Bill which put into the hands of men who need not be, and are not likely to be, physicians or men of science, arbitrary powers requiring for their use skilled knowledge concerning matters of the highest importance to medicine and biological science and to the welfare of mankind. The determined stand made against the Gallinger Bill has had the effect of compelling its authors to amend it to a certain extent, but the only concessions of importance introduced into the Bill drafted in its place relate to exclusion of cold-blooded animals, the omission of two classes of special certificates, and a wider choice in the selection of anæsthetics. In some respects the restrictions are made more severe and the most obnoxious features of the Bill are left unchanged. Professor Eliot of Harvard University expresses the sentiments of the majority of scientific and medical men in this country with regard to all such legislation in the following remarks: "1. To interfere with or retard the progress of medical discovery is an inhuman thing. Within 15 years medical research has made rapid progress, almost exclusively through the use of the lower animals, and what such research has done for the diagnosis and treatment of diphtheria it can probably do in time for tuberculosis, erysipelas, cerebro-spinal meningitis, and cancer, to name only four horrible scourges of mankind which are known to be of germ origin. 2. The human race makes use of animals without the smallest compunction as articles of food and as labourers. It kills them, confines them, gelds them, and interferes in all manner of ways with their natural lives. The liberty we take with the animal creation in using utterly insignificant members of them for scientific researches is infinitesimal compared with the other liberties we take with animals, and it is that use of animals from which the human race has most to hope. 3. The few medical investigators cannot probably be supervised or inspected or controlled by any of the ordinary processes of Government supervision. Neither can they be properly licensed, because there is no competent supervising or licensing body. The Government may properly license a plumber, because it can provide the proper examination boards for plumbers; it can properly license young men to practise medicine, because it can provide the proper examination boards for that profession and these boards can testify to the fitness of candidates; but the Government cannot provide any board of officials competent to testify to the fitness of the medical investigators. 4. The advocates of anti-vivisection laws consider themselves more humane and merciful than the opponents of such laws. To my thinking these unthinking advocates are really cruel to our race. How many cats or guinea-pigs would you or I sacrifice to save the life of our child or to win a chance of saving the life of our child? The diphtheria antitoxin has already saved the lives of many thousands of human beings, yet it is produced through a moderate amount of inconvenience and suffering inflicted upon horses and through the sacrifice of a moderate number of guinea-pigs. Who are the merciful people—the few physicians who superintend the making of the antitoxin and make sure of its quality, or the people who cry out against the infliction of any suffering on animals on behalf of mankind? It is of course possible to legislate against an improper use of vivisection. For instance, it should not be allowed in secondary schools or before college classes for purposes of demonstration only, but any attempt to interfere with the necessary processes of medical investigation is, in my judgment, in the highest degree inexpedient and is fundamentally inhuman." The anti-vivisection party in the United States has been endeavouring to make capital of the supposition that the restrictive laws against vivisection passed some years ago in Great Britain have fulfilled the purpose for which they were enacted and are in harmony with the views of the majority of the scientific and medical men of that country. Dr. Welch, in his address of Feb. 21st showed that such was not the case and demonstrated his point by the contrary evidence of Sir John Simon, Lord Lister, Sir T. Grainger Stewart, Sir T. Lauder Brunton, and Sir Michael Foster. In fact the experience of Great Britain as to the results of restrictive legislation with regard to vivisection will act as an incentive to scientific and medical men to oppose as strenuously as possible the imposition of similar laws in the United States.

June 30th.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund up to noon on Wednesday:—

	£	s.	d.
Christ Church, Lancaster Gate	1519	0	0
Miss M. E. Druce	100	0	0
F. C. D.	100	0	0
Christ Church, Mayfair	174	0	0
Holy Trinity, Roehampton	73	0	0
St. Thomas's, Portman-square	80	0	0
St. James's, Hatcham	97	0	0
St. Augustine's, Highbury	57	0	0
All Saints, Orpington	34	0	0
St. Paul's, Onslow-square	475	0	0
St. Stephen's, Ealing	85	0	0
St. George's, Perry Hill	40	0	0
St. Saviour's, Upper Chelsea	159	0	0
St. Matthew's, Bayswater	142	0	0
Clapham Parish Church	70	0	0
Holy Trinity, Paddington	85	0	0
St. Andrew's, West Kensington	85	0	0
St. Mark's, Hamilton-terrace	223	0	0
Immanuel Church, Streatham-common	72	0	0
St. Michael's, Highgate	82	0	0
St. Matthew's, Denmark-hill	143	0	0
St. Mark's, Highgate	76	0	0
St. Mary Aldermary and St. Thomas Apostle	25	0	0
St. Paul's, Beckenham	145	0	0
St. James's, Piccadilly	88	0	0

The total up to noon on Wednesday last was £31,000. The collection made at Christ Church, Lancaster-gate, is the largest amount ever received from one congregation since the establishment of the Fund.

POPLAR HOSPITAL FOR ACCIDENTS.—The annual festival dinner in aid of the funds of this hospital was held at the Holborn Restaurant on July 2nd, Mr. F. J. Mirrielees presiding. Colonel J. L. du Plat Taylor, replying to the toast of "The Navy, Army, and Auxiliary Forces," said that his son in South Africa had assured him that there were no complaints to make against the hospitals there. It would be better, he thought, if those who had fault to find would communicate with headquarters instead of writing letters to the *Times*. The chairman in proposing "Success to the Poplar Hospital," read a characteristic letter from Mr. Rudyard Kipling, who promised a contribution of £5. The Drapers' Company had given £14,000 for the purpose of providing 20 additional beds for medical cases, and had bestowed an endowment of £1000 per annum. The committee were now appealing for assistance with a view to increase the number of beds. Donations and subscriptions to the amount of about £3900 were announced.

Obituary.

THOMAS JONES, M.B., B.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF SURGERY, OWENS COLLEGE.

WE deeply regret to have to record the death of Professor Thomas Jones at Springfontein, South Africa, under peculiarly sad circumstances. It will be remembered that when it was decided to send out a Welsh hospital to South Africa, Professor Jones consented to undertake the management of it, and he left England on April 14th, together with the other members of the hospital staff. On landing at Cape Town he at once proceeded to Bloemfontein, where he remained for several weeks pending the establishment of the hospital at Springfontein in the Orange River Colony, which he joined towards the end of May. The first intimation of his illness was conveyed in a telegram received on June 16th, stating that he was suffering from nervous prostration. Two days later a message arrived to the effect that he was much better, but the following morning the sad news was received of his death, which had taken place on June 18th, presumably from enteric fever, as a large proportion of the troops under treatment at Springfontein were suffering from this affection. The Manchester contingent of the Welsh Hospital has been strangely unfortunate, for of the five members of the surgical staff who volunteered from this district, two others have also died in South Africa—viz., Dr. Herbert Davies, formerly house surgeon to Professor Jones at the Manchester Royal Infirmary, and also acting in the same capacity in the Welsh Hospital, and Mr. Eames, one of the surgical dressers.

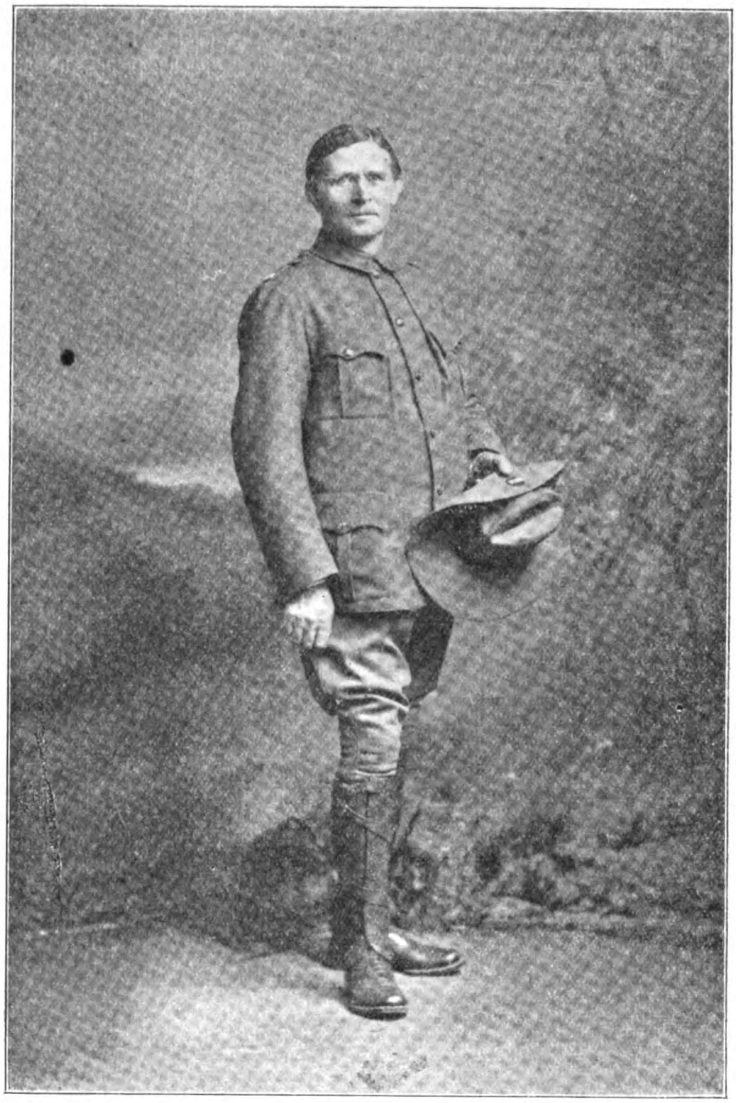
Thomas Jones was born in 1848 in Carmarthenshire, and was educated first at Derlwyn College in that county and afterwards at the Normal College, Swansea. His professional studies were commenced at the Northern Hospital, Liverpool, in 1865, and were continued at Guy's Hospital, London. From an early period in his career his progress was marked by distinction, and he soon gave evidence that he would make for himself a name in the profession which he had decided to follow, for in the examinations for the degree of Bachelor of Medicine of the London University he obtained Honours in Anatomy and Medicine, and the gold medal in Chemistry and Materia Medica. After qualifying he held the office of house surgeon at Guy's Hospital and henceforth devoted himself entirely to the practice of surgery, in which he was destined to rise to such high distinction.

An old Guy's student, one of his contemporaries, writes of him as follows:—

> Probably all old Guy's men who were at the hospital in the late "sixties" and early "seventies" will remember the late Mr. Tom Jones. He was one of the best known students of his year, taking honours in most of the subjects at the London University and carrying off the gold medal in Chemistry at the first M.B. There are many probably who can recall him when dresser to the late Mr. Poland, and somewhat later again as house surgeon. The writer well remembers how well he fitted this latter position and how much he was thought of by the dressers and junior students. He was a perfect mine of information on all sorts of subjects, there was an entire absence of "side" in his manner, and every one liked his cheery disposition and kindly heart. The news of his tragic and untimely death in South Africa comes as a shock to his old fellow-students.

In 1872 Mr. Jones applied for and was elected to the post of house surgeon at the Manchester Royal Infirmary, and from that time he held office continuously at that hospital. From 1873 to 1876 he was pathologist, and from 1876 to 1879 he fulfilled the duties of surgical registrar. In 1875 he obtained the Fellowship of the Royal College of Surgeons of England, and in 1879 he took the degree of Bachelor of Surgery at the University of London with honours. In 1879 he was elected a member of the honorary staff of the Manchester Royal Infirmary, being appointed an assistant surgeon. In 1880, on the death of Mr. S. M. Bradley, he became full surgeon and this office he continued to hold up to the time of his death. In 1874 he was appointed surgeon to the Children's Hospital at Pendlebury, near Manchester, and upon his resignation of that post in 1880 he was made consulting surgeon. In the treatment of surgical diseases of children he always took great interest, and he devoted much time and energy to this institution which at that time had only been recently established. In 1880 he was appointed lecturer on Practical Surgery at the Owens College, and on the resignation of Professor Hare of the chair of Surgery in 1892 he accepted the Professorship of Systematic Surgery. By virtue of the latter office he became Examiner in Surgery to the Victoria University. In addition he also acted as one of the surgeons to the Manchester Cancer Hospital. In 1891 Professor Jones was President of the Manchester Medical Society, in the work of which he had always taken great interest, having been a most active member of the committee from 1875 to 1890. He was also a member of the council of the University College of Wales, in the success of which he was warmly interested and he had contributed generously to its funds.

Professor Jones was a frequent contributor to the medical journals, many of his papers being published in the *Medical Chronicle*, of which he was one of the first and most enthusiastic promoters. His articles were of a highly practical character, being based upon his personal experience and written in a characteristically terse and lucid style. He had always paid special attention to the pathology and treatment of diseases of bone, and in 1887 he published a valuable monograph on this subject which contained the results of his own observations and investigations. We believe that his last contribution to surgical literature was an article upon Injuries and Diseases of the Ankle-joint (written conjointly with Mr. J. E. Platt) which appeared last year in the first volume of the "Encyclopædia Medica" now in course of publication. Professor Jones commenced practice in Manchester on the termination of his tenure of office as house surgeon at the infirmary in 1873 and from the outset he devoted himself entirely to surgery, being one of the first to practise in the provinces as a "pure surgeon." He gradually acquired an extensive consulting practice and for many years he was regarded as one of the leading surgeons in the north of England. He was a most dexterous operator, paying great attention to detail and to the after-treatment of his cases, so that his results were attended by an unusual amount of success. As a teacher Professor Jones had established for himself a great reputation and he was held in high esteem and great respect by the students, with whom he was most popular. He was extremely regular and most indefatigable in his hospital and college duties, rarely allowing the calls of his extensive private practice to interfere with his lectures or classes in the wards.



In private life Professor Jones was the most genial and kind hearted of men. The universal esteem in which he was held was shown by the large and representative attendance at the "send-off" dinner previously to his departure for Africa. The Principal of Owens College was in the chair and among those present were the Lord Mayor, the Dean of Manchester, and many other prominent citizens. A few days later when he left Manchester there was another large assemblage at the railway-station of his personal friends, colleagues, and medical students to wish him God-speed and a safe return.

On Saturday, June 23rd, a memorial service was held in Union Chapel, Manchester (of the congregation of which Professor Jones had been a member), and was very largely attended. Members of the Council and of the teaching staff of Owens College, representatives of the board of management, and almost all the members of the honorary staff of the Manchester Royal Infirmary, together with a large number of medical students, assembled at the College shortly before the time appointed for the service and marched thence in procession to the chapel. An impressive address was there delivered by the Rev. Dr. Maclaren, who described the death of Professor Jones as that of a martyr, and said that his name had been added to the long roll of members of his noble profession who had taken their lives in their hands and freely given them away on behalf of others at the call of duty.

Professor Jones married in 1881 the daughter of Mr. Boyd of Cheadle Hulme. With his widow and an only daughter who survive him very widespread sympathy will be felt in the irreparable loss which they have sustained.

An old student who was house surgeon to Professor Jones writes as follows:—

> The sad and untimely death of Professor Thomas Jones will be keenly and universally deplored by all those of us whose good fortune it has been to have received their surgical instruction under his guiding influence. As a teacher he was always held in the profoundest respect by each one of us, his punctuality and his regularity in attending to deliver his lectures and clinical demonstrations soon earned our warmest appreciation, and many a time did we feel that he had seriously inconvenienced himself in order not to disappoint us. His classes were always largely attended, and his methodical, impressive, and painstaking manner in imparting instruction to us and the kindly and courteous way in which he corrected our errors and listened even to our wildest suggestions made us feel that in him we had a most careful, considerate, and successful

THOMAS JONES, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY, ETC.

teacher, one who thoroughly understood our needs and spared no effort on his part to meet them. And, more than a teacher, we felt him to be our friend in the truest sense—always taking a personal interest in our own individual careers, ever ready to sympathise with us in present misfortunes and to encourage and advise us as to the future, and often has a kindly word from him spurred us on to further efforts, resulting in our ultimate success. His extreme gentleness and consideration towards the patients under his charge, making him beloved by them one and all, has set us a noble example of generous whole-heartedness which we would all do well to follow. When recently it became known that Professor Jones had bravely and cheerfully placed his services at the disposal of the Welsh Hospital, many were the offers from his former students to accompany him to South Africa as his assistants, and proud indeed were the four gentlemen ultimately selected to feel that they were about to help their country's cause under the guidance of one whom they valued and respected so highly. And now, with the hearty "God-speed" with which we took our farewell of the gallant little band still ringing in our ears, comes the sad news that he, of whose unselfish devotion to duty we are all so justly proud, will never return to us again, that his kindly and genial face will never more be seen in the wards with which he will always be so closely associated in our memories, and that we are left to mourn the loss of one who has proved himself a hero in every sense of the word, and our close association and friendship with whom will ever be treasured as one of the pleasantest features of our student days.

HENRY BURFORD NORMAN, F.R.C.S. ENG.

THE announcement of the death of Mr. Burford Norman on June 11th at Chesham, Bucks, has been received with great sorrow by all his friends. His father, Mr. William Norman, was also a medical man and a descendant of an old Somersetshire family—the Normans of Fiveheads. Henry Burford Norman was born on April 11th, 1819, and after a liberal education he commenced his professional training with his father. In 1837 he entered as a student at University College and his companions were Spencer Wells, John Marshall, and John Eric Erichsen. In 1841 he was admitted a Member of the Royal College of Surgeons of England, and soon after was appointed house surgeon to the distinguished Liston. He obtained the Fellowship of the College in 1846 and shortly afterwards he came forward as a candidate for the post of assistant surgeon to University College Hospital, but he was defeated by the late Sir John Erichsen. Mr. Burford Norman then started as an ophthalmic surgeon and he obtained the appointment of surgeon to the North London Eye Hospital. At this period he resided in Duchess-street, Portland-place, W. After a few years of hard work his health became seriously impaired and he was obliged to leave London for rest and retirement. He commenced practice again in 1858 at Portsmouth as the successor of the late distinguished surgeon, Dr. E. J. Scott. In 1861 he was elected on the surgical staff of the Royal Portsmouth Hospital, an appointment which he held with marked distinction for several years. He took a leading part in the foundation of the Portsmouth and South Hants Eye and Ear Infirmary, and filled the position of consulting surgeon to that institution. Mr. Norman was an able and well-known surgeon in Hampshire and he practised with much success for many years. He contributed many valuable papers on surgical topics to the medical journals. He was a Fellow of the Royal Medical and Chirurgical Society and an ex-President of the Harveian Society. Throughout his long career he enjoyed the entire confidence of the medical men of Portsmouth, and on his retirement from practice in 1889 he was entertained at dinner by his professional friends and was presented with a valuable silver service as a token of their regard and esteem.

Mr. Burford Norman was a man of sterling character and ever ready to help in every good and worthy enterprise. He was twice married and has left behind him a widow and six children. Two of his sons are members of the medical profession. By a life guided by broad and charitable sentiments and never-failing courtesy he obtained the affection and confidence of a large circle of friends.

HENRY PEACOCK, F.R.C.S. ENG., M.R.C.P. LOND.

MR. HENRY PEACOCK died at Bath on June 12th in his eighty-eighth year. Mr. Peacock received his medical education at the London Hospital and qualified as M.R.C.S. Eng. in 1837. Two years later he entered the medical service of the Royal Navy. In 1839–40 he was assistant surgeon on H.M.S. *Crocodile*, at that time engaged in suppressing the slave-trade. Mr. Peacock was afterwards appointed medical officer to the dockyard at Chatham, a post which he held for nearly 20 years, and was also staff surgeon to the Royal Dock yard Battalion from its formation until his retirement from the service. Mr. Peacock became F.R.C.S. Eng. in 1852 and 10 years later was admitted a Member of the Royal College of Physicians of London. In 1862 he commenced practice at Sudbrook (Gloucestershire) and was subsequently appointed assistant physician to the Gloucester General Infirmary and medical officer to the Gloucester Provident Dispensary. Mr. Peacock, who had retired from the practice of his profession, had recently resided at Malvern.

ARCHIBALD ADAMS, M.D., M.CH. R.U.I., F.R.C.S. IREL.,

LIEUTENANT-COLONEL INDIAN MEDICAL SERVICE.

LIEUTENANT-COLONEL ARCHIBALD ADAMS, I.M.S., succumbed to an attack of cholera at Mount Abu on May 20th. He was born on March 20th, 1850. He was educated at the Royal University of Ireland and graduated M.D., M.Ch., in 1872, subsequently taking the Fellowship of the Royal College of Surgeons in Ireland in 1886. He entered the Medical Department of the Navy, passing through the Netley School in the winter session of 1872–73, and served in Africa with the Royal Marines during the Ashanti war of 1873–74, for which he received the medal. In the spring of 1875 he competed for an appointment in the Indian Medical Service and was gazetted a Surgeon on the Madras Establishment on March 31st of that year. He was duly promoted to field rank in 1887, and on March 31st, 1895, attained the rank of Lieutenant-Colonel. Not long after his arrival in India he was posted as medical officer of the Erinpoora force, a local corps under the orders of the Indian Foreign Office, and he continued under the Foreign Office during the remainder of his life. Promotion soon came to him from regimental employment to the important post of Residency Surgeon at the Court of Marwar, where, at the capital, Jodhpore, he resided for some 18 years, supervising all the medical arrangements of that wealthy State and enjoying not only a lucrative practice but also the respect and esteem of a succession of British Residents at the Court and of a circle of native friends which included the two successive Maharajas Jaswant Singh, G.C.S.I., and Sardar Singh. Only last year Lieutenant-Colonel Adams published a medico-topographical and general account of the Western Rajputana States, of which he had a rare knowledge. This work is one of great excellence, showing a mastery of facts and bearing evidence of the industry with which he applied himself to the study of the conditions affecting the health and happiness of the inhabitants of that portion of India in which his lot was cast. His hospitality while at the Court of Jodhpore was remarkable even in the hospitable community of Anglo-Rajputs, and his kindness of heart and skill will long be remembered by a very wide circle of friends who admired the sterling traits of his character.

From Jodhpore Colonel Adams was promoted to be Administrative Officer in Rajputana—a post which is regarded as the blue ribbon of the Foreign Office appointments. He has now fallen at his post of duty, a victim to that fell disease which is following in the wake of famine and is now adding to our great difficulties in India. Lieutenant-Colonel Adams was attacked by the disease at Mount Abu at the time when at Pallanpur (near Abu Road) 25,000 famine-stricken people were in the grip of cholera—and cholera of such a virulent type that some of the victims are said to have succumbed within 10 minutes of the appearance of the symptoms.

Lieutenant-Colonel Adams married only a few years ago a daughter of Lieutenant-Colonel H. B. Abbott, who was many years Political Agent at the Court of Jhallawar. To this lady our thoughts of true sympathy are extended in these days of her sudden bereavement.

CLAUDE CLARKE CLAREMONT, M.R.C.S. ENG., L.S.A.

MR. CLAUDE CLAREMONT, who died at Bognor on May 27th, in the 77th year of his age, was a well-known practitioner in North London and had an exceptionally long record of service as public vaccinator to St. Pancras parish. He received his professional education at University College, London, becoming qualified as M.R.C.S. in 1855 and as L.S.A. in 1859. In 1858 he contributed to THE LANCET an interesting case in which during the extraction of several teeth under chloroform a portion of a tooth slipped into the larynx unperceived by anyone, the first symptom of the

mishap being the fits of coughing and respiratory difficulties produced by the foreign body. The fragment of tooth was expelled on the thirty-fourth day afterwards during a fit of coughing and was found to weigh seven grains. In October, 1899, Mr. Claremont retired from practice and on this occasion a brief notice of his long public service appeared in THE LANCET of Nov. 18th (p. 1392). Mr. Claremont had seven sons, three of whom are medical men, one practising in London, one in Southsea, and one in Norwich.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE twelfth election of Fellows to fill the vacancies in the Council of the College under the new regulations was held at the College, Lincoln's Inn-fields, on Thursday, July 5th, between 1.30 P.M. and 4 P.M. The result of the voting was as follows:—

	Votes.	Plumpers.
MR. A. COOPER	304	16
MR. J. WARD COUSINS...	257	16
MR. A. PEARCE GOULD...	253	6
MR. J. TWEEDY	233	2
MR. J. BLAND-SUTTON ...	199	13
MR. R. CLEMENT LUCAS ...	170	32
MR. W. J. WALSHAM... ...	159	1
MR. H. H. CLUTTON... ...	148	11
MR. G. JORDAN LLOYD ...	138	3
MR. C. H. GOLDING-BIRD...	127	5
MR. W. H. BENNETT... ...	121	8
MR. J. A. BLOXAM	83	7

Mr. Tweedy and Mr. Cooper are therefore re-elected and Mr. Ward Cousins and Mr. Pearce Gould elected Members of the Council.

713 Fellows voted, 34 personally and 679 through the post. 4 proxies arrived too late and 3 voting papers were spoiled. The number of candidates, 12 for the four vacancies, made the election remarkable.

Medical News.

MR. BURDETT-COUTTS'S CHARGES: APPOINTMENT OF THE COMMISSION.—Mr. Balfour announced in the House of Commons on Thursday afternoon that Dr. W. S. Church, President of the Royal College of Physicians of London, Professor Daniel John Cunningham, Professor of Anatomy, Trinity College, Dublin, and Lord Justice Romer, would constitute the Commission of Inquiry to investigate the treatment of the sick and wounded in South Africa.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations have been admitted Licentiates in Dental Surgery and have received their diplomas:—

Robert Westmore Allen and John Bennett, Guy's Hospital Dental Department and School; Thomas Algernon Baker, Mason College, Queen's, General, and the Dental Hospital, Birmingham; Mountjoy Henry Bartlett, Wilfrid Boothby Blandy, and Herbert Bristow, Charing Cross and the Dental Hospital of London; Charles James Burton and Arthur Ernest Chaundy, Middlesex and the National Dental Hospital; Giovanni Battista Ciceri, M.D. Pavia, University of Pavia, Italy, and the Dental Hospital of London; Ernest Couchman, Guy's Hospital Dental Department and School; Henry Ormrod Dickin and Edward Entwisle, University College, Royal Infirmary, and Dental Hospital, Liverpool; Alfred Culmer Edwards, Percy Harry Furnivall, Arnold Maurice Gabriel, and John Herbert Greenwood, Guy's Hospital Dental Department and School; Claude Bolton Grenside, Robert Harold Heath, Arthur George Heydon, and Robert Hooper, Charing Cross and the Dental Hospital of London; George Henry Hiorns, Middlesex and the National Dental Hospital; Robert Howard, Ernest Guy Jones, and Samuel Kersh, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester; William Jarvis, Leonard Adolphus Charles Knight, and Athol Lucien Lambert, Guy's Hospital Dental Department and School; William Kittow, Charing Cross and the Dental Hospital of London; Everard Foster Lane and Thomas Charles Mills, Middlesex and the Dental Hospital of London; Hector Ernest Laurence, Middlesex and the National Dental Hospital; Rowland Claude Gasson May, Charles Sculthorpe Morris, Kenneth Carrington Ness, and Sydney Lionel Prall, Guy's Hospital Dental Department and School; Percy George Pavitt and George Frederick Prickett, Middlesex and the National Dental Hospital; Walter Leslie Pearse, Charing Cross and the Dental Hospital of London; Horace Reginald Pring, M.R.C.S. Eng., St. Thomas's and the Dental Hospital of London; Ralph Bertram Recordon, William Radley Searle, Harvey Llewellyn Shelton, and Alfred Montague Austin Stevens, Guy's Hospital Dental Department and School; Samuel Henry Roe, Harold Round, and Herbert Steynor Steynor, Mason College, Queen's, General and the Dental Hospital, Birmingham; Ernest George Simmonds, M.R.C.S. Eng., St. Bartholomew's and the National Dental Hospital; Percival Frank Swabey, Albert Edward Toogood, William White, and Reuben Archibald Winder, Charing Cross and the Dental Hospital of London; John Newsome Taylor, University College Royal Infirmary and Dental Hospital, Liverpool; and Jacob Louis Wartski, Guy's Hospital Dental Department and School.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in the subjects indicated:—

Monday, July 2nd:

Anatomy and Physiology.—Henry William John Hawthorn, Herbert Frank Marshall, Seymour Gilbert Barling, Cuthbert Keary Gettings, Robert Beatson Dennis Hird, James Archibald McIlroy, and Edward Brown Garrard, Mason University College, Birmingham; Ian Canute Gordon Glassford, Melbourne and Edinburgh Universities; Harry Reginald Burpitt and Hector Jones, University College of South Wales, Cardiff; Edward Aubrey Guy Wilkinson, Oxford University; George Hamilton, Otago University and Middlesex Hospital; William Tudor Webb, University College, Bristol; Harold Joseph Moon, Owens College, Manchester; William Phillips Jones, Firth College, Sheffield; George Raymond, St. Thomas's Hospital; Frank Herbert Wood, George Henry Adam, and William Bradshaw Ainger, St. Bartholomew's Hospital; Norman Bremer Vickers Jacob, London Hospital; Gerald Eade Bellamy, Charing Cross Hospital; and Arthur Frederick Cole, St. Mary's Hospital.

14 gentlemen were referred to their professional studies for three months.

Tuesday, July 3rd:

Anatomy and Physiology.—Wilfrid Ashwell Aldred, Thomas Waycott Chaff, John Wheeler Cleveland, Frederick Spencer Lister, and Harry Theodore Wilson, St. Bartholomew's Hospital; John Avery, Harold Munro Scott, and Cecil Colmer, London Hospital; Herbert Ernest Batten, Edward Guy Anthonisz, and Rupert Butterworth, St. Mary's Hospital; William Athol Desmond King, Middlesex Hospital; Welby Earle Fisher, Philip Henry Seal, and Isidor Tritsch, University College, London; Ernest Ulysses Williams, Sebastian Gilbert Scott, and George Hope Warren, King's College, London; Malcolm Winfrid Shutte and Philip Reginald Humphry, St. George's Hospital; Bernard Higham and James Hornidge Chauncy, St. Thomas's Hospital; Robert Edward Brayne, Walter Woolfe Read, and Guy Leslie Buckridge, Guy's Hospital.

11 gentlemen were referred to their professional studies for three months.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Alessandro Codivilla of Turin has been recognised as *privat-docent* of Surgery.—*Chicago (Rush Medical College):* Dr. Daniel R. Brower has been appointed Professor of Neurology and Psychiatry. Dr. W. H. Welch, of the Johns Hopkins University, has been appointed Professor of Therapeutics and Materia Medica.—*Genoa:* Dr. Carlo Orrecchia of Turin has been recognised as *privat-docent* of Surgery.—*Gratz:* Dr. A. Birnbacher, extraordinary Professor of Ophthalmology, has been appointed ordinary Professor.—*Jena:* Dr. Hartmann has been recognised as *privat-docent* of Surgery.—*Leipsic:* An institute of forensic medicine has been recently established, the charge of which has been intrusted to Professor Kockel.—*Lille:* Dr. Calmette has been appointed Professor of Hygiene and Bacteriology.—*Messina:* Dr. Ernesto Tricomi of Padua has been appointed Professor of Clinical Surgery and Operative Medicine.—*Montpellier:* Dr. Bosc has been appointed Professor of Pathological Anatomy.—*Prague (Bohemian University):* Dr. Franz Scherer, *privat-docent* of Diseases of Infants, has been promoted to an extraordinary Professorship.—*St. Petersburg (Military Medical Academy):* Dr. Blumenau has been recognised as *privat-docent* of Internal Medicine and Dr. Oleinikoff as *privat-docent* of Bacteriology.—*Strasburg:* Dr. Funke has been recognised as *privat-docent* of Midwifery and Gynæcology and Dr. Landolt as *privat-docent* of Ophthalmology.—*Yale:* Dr. Moses C. White, Professor of Pathology for the last 33 years, has become Emeritus Professor; Dr. Bartlett has been appointed to succeed him. Dr. Benjamin Moore, Professor of Physiology, has resigned, having been appointed to the Lectureship in Charing Cross Hospital, London. Dr. Otto G. Ramsay of the Johns Hopkins University has been appointed to the Chair of Obstetrics and Gynæcology.

METROPOLITAN HOSPITAL SATURDAY FUND.—Oct. 13th is the date set apart for the "Special" Hospital Saturday Collection for the current year.

THE LIVINGSTONE MEDICAL COLLEGE.—The committee of this institution has purchased the mansion, which includes about two acres of adjoining woodland, lately in the occupation of the Barclay family of Knotts Green, Leyton, Essex. The college is intended for the primary medical training of candidates for foreign missionary work.

PRESENTATIONS.—Mr. Richard Ellery, L.R.C.P., L.M. Edin., M.R.C.S.Eng., L.S.A., who is leaving Plympton, Devon, after a residence in the village of 35 years, was on June 16th presented with a silver salver together with a list of the subscribers, numbering about 150. Mrs. Ellery was presented with a purse of gold.—On the occasion of his recent marriage the Æsculapian Society of London presented Mr. W. Campbell M'Donnell, L.R.C.P. Lond., M.R.C.S., with a table and chair for his consulting room, a gratifying recognition of his services as honorary secretary to the Society.

GUY'S HOSPITAL PRIZE DAY.—On July 4th at a garden party given by the governors and medical staff of Guy's Hospital, the prizes and medals were presented to the successful students by the Right Hon. the Earl of Pembroke and Montgomery, G.C.V.O. A large company assembled in the theatre in the new school buildings to witness the ceremony, Mr. Cosmo Bonsor, M.P., being in the chair. After Lord Pembroke had given the awards and addressed the students and guests, Dr. Frederick Taylor moved a vote of thanks to his lordship, which was seconded by Dr. Stevenson. A move was then made to the grounds, where the band of the Scots Guards played a lively selection of melodies. The hospital and school buildings were opened for inspection, and refreshments were served in the quadrangle of the surgical buildings.

THE CONVERSAZIONE AT THE POLYCLINIC.—The conversazione given by the president and council of the Medical Graduates' College and Polyclinic on July 4th was a most successful affair. About 900 medical men were present. The occasion was the inauguration of the museum and an oration by Professor Osler of Baltimore on the Teaching of Practical Medicine. The ceremony of inauguration by the President, Sir William Broadbent, Bart., was witnessed by a crowded assembly who accorded Mr. Hutchinson, after whom the museum is named, a hearty reception. The oration was then delivered in the lecture hall by Professor Osler, who spoke for nearly an hour and whose words elicited much applause. The entire building was then thrown open for inspection and, in addition to demonstrations and exhibitions in the different departments, a good programme of music by the London Orchestral Band enlivened the proceedings.

SOCIETY FOR THE STUDY OF CHILDREN'S DISEASES.—On June 11th a well-attended meeting took place at 20, Hanover-square, London, W., for the purpose of discussing the advisability of founding a society for the study of children's diseases. Dr. Arthur E. Sansom occupied the chair. Mr. Clement Lucas proposed and Dr. Fletcher Beach seconded the following motion—viz., "That in the opinion of this meeting it is advisable to form a society for the purpose of studying the diseases of children." The motion was supported by several speakers, including Dr. E. Cautley and Dr. W. C. Chaffey (Brighton) and Mr. J. Jackson Clarke, Mr. F. Churchill, and Mr. Alfred H. Tubby. After some discussion, during the course of which it was stated that the new society would be largely clinical, and that its meetings would probably be held at the various hospitals in London and in the provinces, Mr. Lucas's motion was carried *nem. con.* A provisional committee, consisting of the following gentlemen, was appointed to draw up rules and to make necessary arrangements:—Mr. Henry G. Armstrong (Wellington College), Dr. Henry Ashby (Manchester), Dr. Wayland C. Chaffey (Brighton), Dr. Arthur Downes (Local Government Board), Mr. Walter Edmunds, Dr. Theodore Fisher (Bristol), Mr. Jonathan Hutchinson, sen., Dr. David B. Lees, Mr. Clement Lucas, Mr. Howard Marsh, Dr. Lewis Marshall (Nottingham), Dr. John McCaw (Belfast), Mr. D'Arcy Power, Dr. Humphry D. Rolleston, Dr. Arthur E. Sansom, Dr. George E. Shuttleworth, Dr. Harold J. Stiles (Edinburgh), Dr. George A. Sutherland, Mr. Alfred H. Tubby, Dr. Dawson Williams, and Mr. Sydney Stephenson (honorary secretary *pro tem.*).

MEDICAL MAGISTRATE.—The Lord Chancellor has appointed Mr. C. H. Johnson, M.R.C.S., a Justice of the Peace for the borough of Basingstoke.

DR. JOHN CROPPER was on June 25th returned at the head of the poll at the Port Skewett (Mon.) School Board election.

CENTENARIANS.—Sarah Priest, who is in her 104th year, applied to the Bath Board of Guardians on June 13th for outdoor relief.—Miss M. A. G. Strachan, who celebrated her 100th birthday in February last, died at College-green, Bristol, on June 18th.

A CURIOUS DENTAL ACCIDENT.—A curious accident is reported in the *Indian Medical Record* of June 6th. A boy, aged nine years, whilst attending a cow was horned by it in the face. The effect of the blow was to drive the left central incisor through the alveolar process into the incisor fossa, from which it was easily removed by means of suitable forceps. The remarkable feature about the accident was that the blow inflicted no other injury in the mouth. The tip of the horn must just have caught the cutting edge of the incisor tooth.

THE NEW JENNY LIND INFIRMARY FOR SICK CHILDREN, NORWICH.—On June 30th the Prince and Princess of Wales were present at the formal opening of this institution. The ceremony was performed by the Princess. This infirmary has been erected as a memorial of the Queen's Diamond Jubilee at a cost, including equipment, of £14,000. For the endowment fund the sum of £10,000 has been subscribed, but £4000 are still required. It may be stated that Mr. Otto Goldschmidt, husband of the late Madame Jenny Lind, and their son and daughter witnessed the interesting ceremony.

AMERICAN ODDFELLOWS AND THE FAITH-HEALERS.—The Supreme Lodge of the Knight of Honour of the United States, which is stated to be the most powerful body of Oddfellows in America, has decided to decline as members all persons associated with the body known as Christian Scientists. Statistics in America prove that the mortality amongst the faith-healing fraternity, who decline the services of medical men, is so high that their membership in a society of persons coöperating for mutual general assistance becomes very undesirable.

SHORTHAND FOR MEDICAL STUDENTS.—The Society of Medical Phonographers offers for competition among registered medical students two prizes, each of the value of £5, one for those studying in England and one for those studying in Scotland or Ireland, for proficiency in the groundwork of phonetic shorthand (phonography). A second prize will be given in each case, consisting of one year's free membership of the society and a selection from its shorthand publications. The examination will be held the first week in November simultaneously in London, Edinburgh, and Dublin, and at any provincial medical school in the United Kingdom at which not fewer than three candidates shall offer themselves. Intending candidates are requested to send in their names at as early a date as possible to the examination secretary (Dr. E. B. Gray, Oxford), who will inform them in due course as to the precise date and place of examination at each centre.

LITERARY INTELLIGENCE.—Messrs. Rebman, Limited, announce the following new books as just issued:—"The International Text-book of Surgery," by British and American authors, in two volumes, edited by A. Pearce Gould, M.S. Lond., F.R.C.S. Eng., of the Middlesex Hospital, and J. Collins Warren, M.D., LL.D., of Harvard Medical School; "An Entirely New Cyclopædia of Practical Medicine and Surgery," in one volume, illustrated, by 70 special contributors, compiled under the editorial supervision of Dr. George M. Gould and Dr. Walter L. Pyle of Philadelphia; "A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease," by Dr. Arthur R. Cushny; "The Gross and Minute Anatomy of the Central Nervous System," by Dr. H. C. Gordinier; "Gould's Year-book of Medicine and Surgery for 1900," in two volumes (Medicine and Surgery).—The same publishers also announce the following for early publication: Vol. II. of Professor

Deaver's work on "Surgical Anatomy"; a new book by Mr. A. Marmaduke Sheild entitled "The Causes, Consequences, and Treatment of Nasal Obstruction"; and "A Treatise on the Theory and Practice of Medicine for Students and Practitioners," by Dr. H. W. Syers of the Great Northern Central Hospital, London.

EDINBURGH UNIVERSITY UNION.—On Friday, June 29th, an interesting dinner was given in the Royal Hotel, Edinburgh, by members of the classes of surgery, midwifery, and clinical surgery of the University of Edinburgh. The dinner was in honour of Mr. H. J. Stiles, Dr. W. Fordyce, and Mr. Bowden, the assistants in the above classes, who were retiring from their respective posts. Mr. J. C. Mitchell, D.Sc., presided over a gathering of more than 100 gentlemen, among whom were Dr. G. A. Gibson, Mr. F. M. Caird, Dr. F. W. N. Haultain, and other colleagues of the guests.

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The annual general meeting of this association took place on July 3rd at the Café Royal, Regent-street. Dr. J. R. Gabe was elected President for the forthcoming year and Dr. A. L. Achard Vice-president. Dr. E. G. Younger and Dr. Major Greenwood were unanimously re-elected respectively treasurer and honorary secretary. The members and their friends afterwards dined together. After the usual loyal toasts, Mr. Howard Marsh proposed the "Health of the Association." This was responded to by Dr. Greenwood, who said that the association was not in favour of the reciprocity scheme brought before the General Medical Council at its last session, and that although their members claimed the right to register foreign degrees in addition to English qualifications they were strongly opposed to the registration of practitioners possessing only foreign ones. The President proposed "Our Guests," and the toast was responded to by Dr. Vivian Poore and Dr. Gilbart Smith. The Amphion Gleemen, under the direction of Mr. Sidney Marion, gave a selection of glees and songs during the evening.

NEW PHYSICAL LABORATORY FOR OWENS COLLEGE.—The new physical laboratory of Owens College, Manchester, was opened on June 29th by Lord Rayleigh. The building stands opposite to the College in Coupland-street, contains about 40 rooms, and is provided with a great variety of valuable apparatus and machinery. On the roof there is an observatory with a 10-inch telescope. The electro-chemical and electro-technical departments are specially dedicated to the memory of Dr. John Hopkinson. A sum of £23,000 has been laid out upon the building and a further amount of £10,000 is to be spent upon the equipment. The executors of the late Mr. John Harling have given £5000 for the purpose of endowing a research Fellowship. In declaring the building open Lord Rayleigh said that Professor Arthur Schuster who presides over the laboratory was an old friend of his, and that 20 years years ago they worked together on the subject of electrical units. When he was a young man he had not at his disposal anything approaching the facilities for practical and experimental work which were to-day provided in this laboratory.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Registered Companies and Medical Practice.

ONE of the clauses of the Companies Bill proposes that it shall be unlawful for a registered company to carry on medical practice. Another says that no such company may carry on the business and use the description of a pharmaceutical chemist or chemist and druggist unless the business is *bonâ fide* conducted by a manager or assistant who is duly registered. Both these clauses were discussed on Tuesday, July 3rd, when the Bill came before the Grand Committee of the House of Commons on Trade. Mr. RITCHIE the Minister in charge of the Bill, suggested that they should be deleted, giving as his opinion that they were not germane to the Bill and that their appearance in it would jeopardise its passage. Sir HENRY FOWLER defended the clauses as both appropriate and necessary, and the majority of the Committee taking the same view determined by 17 to 12 votes to retain both clauses. Mr. MARKS proposed to insert in the medical clause words to the effect that nothing in it should prevent a company from making a contract with a physician or surgeon for services rendered or to be rendered at the request of the company, or from making any contract with any person in respect of the services of a physician or surgeon who is under contract with the company. The ATTORNEY-GENERAL gave the opinion that the amendment was unnecessary, and Mr. Marks did not press it.

Amendment of the Medical Acts.

The Bill drafted by the General Medical Council for the amendment of the Medical Acts will be introduced into the House of Commons on Friday, July 13th, by Sir RICHARD JEBB, one of the Members for the University of Cambridge. The Bill deals mainly with the disciplinary powers of the General Medical Council and the medic licensing authorities.

HOUSE OF COMMONS.

THURSDAY, JUNE 28TH.

Volunteer Medical Officers.

Sir HOWARD VINCENT asked the Under-Secretary of State for War if, having regard to the fact that the medical experience of a surgeon in the volunteer force could not be increased by his watching men going through field training for 14 days, the pay and allowances of one medical officer for the whole period of camp could be sanctioned and its allotment be left to the commanding officer among such of the surgeons of a regiment whose practice enabled them to be present on certain days.—Mr. WYNDHAM: The suggestion will be considered.

Inoculation of the Troops against Enteric Fever.

Mr. WYNDHAM, replying to a question on this subject, said that the operation was entirely voluntary. There was no idea of making an experiment on the troops going out to South Africa. The credit of suggesting inoculation belonged to the Professor of Pathology at Netley Hospital.

The St. Pancras Lunacy Scandal.

Mr. JOHN BURNS asked the President of the Local Government Board whether he had considered the advisability of holding a Local Government Board inquiry into the irregularities committed by the relieving officers of St. Pancras.—Mr. CHAPLIN: I have directed an investigation by the Local Government Board into this matter. Pending the inquiry I have directed a communication to be made to the metropolitan boards of guardians to the effect that in the opinion of the Board such practices are altogether indefensible.

FRIDAY, JUNE 29TH.

Army Medical Department.

Sir CHARLES DILKE asked the Under-Secretary of State for War whether the report of the Departmental Committee which was sitting in 1898 on the Re-organisation of the Army Medical Department was presented to Parliament, and if not, whether the portion of it which bore on organisation for war could now be laid before Parliament.—Mr. WYNDHAM replied: The Committee to which the right hon. baronet referred only considered the titles to be given to the corps and to the officers and the command to be exercised by the officers. No question of organisation came before it.

Sir Walter Foster's Offer to the War Office.

Sir HENRY FOWLER asked the Under-Secretary of State for War whether, in October last, he received a letter from the honourable Member for Ilkeston (Sir Walter Foster) pointing out that in all probability great loss of life from fever and other maladies, more or less preventable by careful sanitary work, was likely to occur in the South African campaign, and suggesting the appointment of a small sanitary commission, or a commissioner and assistants, to proceed to South Africa to assist the army medical officers in preventing the dangers referred to; whether the honourable Member offered to place his services and his experience as a physician and as secretary of the Local Government Board during the last invasion of cholera, at the disposal of the War Office in an unpaid capacity; and whether the suggestion and offer were declined by the Secretary of State on the ground that the need of special assistance was not the same in sanitary matters as in surgical operations.—Mr. WYNDHAM replied: Yes, sir; the facts are as stated. Army surgeons are not in constant practice as operators, and therefore the Secretary of State was very glad to avail himself of the patriotic offers made by Sir W. Mac Cormac, Mr. Treves, and other specially skilled surgeons. But army medical officers have special training in sanitation of camps and the management of diseases incidental to field service and abundant opportunities of obtaining experience in these matters. It did not, therefore, appear that there was any occasion for the appointment of such a sanitary commission as the hon. Member proposed.

Strength of the Medical Staff in South Africa.

Mr. WYNDHAM, replying to questions on this subject, said that for each increase of the force in South Africa a proportionate increase of medical staff and medical stores had been made. There were now in South Africa, according to their latest information, 466 army medical officers and 440 civilian surgeons, 566 female nurses, and 5668 male nurses and orderlies. These did not include doctors and nurses engaged in South Africa. The supply of beds was on June 16th 5000 in Natal and 13,600 in Cape Colony and other parts, total 18,600 beds in South Africa.

Debate on the Medical Arrangements in South Africa.

The House devoted nearly eight hours of this sitting to a debate on the medical arrangements in South Africa which had been impugned by Mr. Burdett-Coutts in a series of articles in the *Times* and had been the subject of question and answer across the floor of the House at several previous sittings. The debate took place in Committee of Supply, the Government putting up for the purpose a purely nominal supplementary vote for the Army Medical Department. The speeches delivered were too numerous and dealt too much with matters of detail to be reported or even to be summarised in this column and no doubt our readers will have seen reports of them in the

day press. Before the debate began Members had in their hands copies of a telegram from Lord Roberts in which his lordship suggested that a small committee should be deputed to proceed to South Africa in order to inquire into and furnish a full report on the working of the medical arrangements throughout the war, and they had before them the promise of Mr. Balfour that the Government would adopt this suggestion.

MONDAY, JULY 2ND.

Inoculation against Typhoid Fever.

Mr. JOSEPH A. PEASE asked the Under-Secretary of State for War whether the medical expert at Netley Hospital who recommended the inoculation with so-called anti-typhoid serum of troops sent to South Africa had sold serum to the Government; if so, how many doses were purchased from him, and at what price; and whether the doctor had pecuniarily profited by the sale of serum.—Mr. WYNDHAM: No, sir, there is no pecuniary profit.—Mr. PEASE: Were any doses sold?—Mr. WYNDHAM: My information is that there was no sale or profit to anybody concerned.

Outfit Allowance for the Royal Army Medical Corps.

Mr. MACNEILL asked the Financial Secretary to the War Office would he explain why, when all officers of the Reserve rejoining under Paragraph 483, Clause C, of the Royal Pay Warrant (whether ordered on active service or otherwise), had been granted an outfit allowance of £100 to cover the expense of providing themselves with the necessary uniform, exception had alone been made in the case of officers of the Royal Army Medical Corps, and would he say whether the word "officer," used in Part I. of the Royal Warrant, included medical as well as officers of any other corps.—Mr. POWELL WILLIAMS: Outfit allowance will be granted in these cases.

Medical Men and the Housing of the Working Classes.

Sir WALTER FOSTER during the report stage of the Housing of the Working Classes Act (1890) Amendment Bill moved to insert in the Bill the following new clause—viz.: 1. "It shall be the duty of the medical officer of health of every rural sanitary district to represent to the local authority of that district any parish or other area within that district where danger arises to the health of the inhabitants of such parish or area from the insufficiency or unwholesomeness of the existing supply of lodging-houses for the working-classes. 2. If in any rural sanitary district any four or more householders living in or near to any parish or other area in such district complain in writing to the medical officer of health of that district that danger arises to the health of the inhabitants of such parish or area or of such district from the insufficiency or unwholesomeness of the existing supply of lodging-houses for the working-classes in such parish or area he shall forthwith inspect the same and transmit to the local authority the said complaint and his opinion thereon, and if he is of opinion that danger does arise as aforesaid shall represent such parish or area to the local authority, but the absence of any such complaint shall not excuse him from the duty of making a representation under sub-section one of this section when necessary. 3. If within three months after receiving the said complaint and opinion or representation of the medical officer the local authority declines or neglects to take any proceedings to put this part of the Act in force, the householders who signed such complaint may petition the Local Government Board for an inquiry, and the said Board after causing an inquiry to be held may order the local authority to proceed under this part of this Act, and such order shall be binding on the local authority." Sir Walter Foster said he was anxious that there should be some means of calling the attention of the local authority to their neglect of the intentions of the Legislature and he could not think of any more suitable means than the medical officer of health who was familiar with the conditions and circumstances of the locality. With regard to the third sub-section of the clause he was aware that there might be objection to the interference of the Local Government Board and therefore he would be prepared to substitute the County Council.—Mr. CHAPLIN, the Minister in charge of the Bill, intimated that he could not accept the clause. He was advised, and he was satisfied, that much that the hon. Member had in contemplation could be done under the existing law. He attached great importance to the medical officer of health, but he did not think the position of that officer would be improved by this clause. The position of the medical officer of health would have to be considered some day. To make him really efficient he would have to be put in quite a different position from his present position, but the thing would require to be done in a Bill for the amendment of the Public Health Acts; he did not think it could be dealt with in this Bill. With regard to the third sub-section, he had considered the matter very carefully, and he had come to the conclusion that if pressure of this kind was to be brought to bear it should be brought to bear through the County Council and not through the Local Government Board. The former was a representative body and it had the great advantage of local knowledge.—After some further discussion Sir WALTER FOSTER withdrew his proposed new clause, and there was inserted in the Bill a clause empowering the County Council to take action in cases where the rural council had been guilty of default.

PROPOSED EXEMPTION OF HOSPITALS FROM LOCAL RATES.

EVIDENCE BEFORE THE SELECT COMMITTEE.

The Select Committee of the House of Commons appointed to inquire into the proposed exemption from local rates of hospitals and institutions for the education and treatment of idiots and imbeciles met again on Friday, June 29th, with Mr. T. W. RUSSELL, Parliamentary Secretary to the Local Government Board, in the chair, and proceeded with the examination of witnesses.

Sir WILLIAM HART DYKE, M.P. for the Dartford division of Kent, explained that owing presumably to the salubrity of the district of Dartford there had been planted there a large number of charitable institutions, some supported wholly by voluntary contributions and others rate-aided, proceeding directly or indirectly from Acts of Parliament, and he submitted that in the matter of rating a clear distinction should be drawn between institutions planted in such a district on behalf of the inhabitants of a distant community and supported by these inhabitants and institutions designed to meet purely local wants. At the present moment contracts were out for the construction of a small-pox hospital in the district which was to cost over £200,000. If such an institution were exempted from rates he thought the locality would have a distinct grievance and he would remind the Committee that institutions of this description were a nuisance and a detriment to the prosperity of a district. Already they had in the district institutions metropolitan in character and object, such as a home for waifs and strays, convalescent homes, an asylum for idiots, and the City of London Asylum. He thought it would be a great hardship to the Isle of Wight if the Hospital for Consumption at Ventnor were exempted from local rates, seeing that the institution was designed for the use of patients from a distance. In the case of the cottage hospital at Dartford, a local institution, no rates were paid. He would not like to leave the rating of hospitals to the discretion of local authorities, because the result would be uncertain; he would rather have the matter settled once and for all by Parliament. He frankly admitted that the case was not free from difficulty, especially when they had to deal with institutions which were both local and general in their character.

Mr. BARTON, Commissioner of Valuation in Ireland, called in connexion with the evidence given by Mr. Manders of the Irish Office, gave an account of the system of valuation in Ireland. He explained that there were no local valuation committees in Ireland, the whole valuation work of the country being done by his department. He cited the Acts of Parliament which govern that work and which exempt from local rates institutions used exclusively for scientific and charitable purposes. In Dublin, where there were many hospitals, some with paying beds, none paid rates, and the corporation in addition contributed £10,000 or £11,000 every year towards the cost of the maintenance of the hospitals. There was a feeling in Dublin that exemptions had been carried too far and probably some change would be made in the future. He was now engaged in the revision of the valuation of Belfast, and he proposed, subject of course to the appeal of the courts which was always open to those concerned, to make a change in his procedure. He proposed in the case of hospitals with paying beds to make two valuations—one in respect of the paying beds and the other in respect of the free beds. The latter would be free from rates, while the former would have to pay a certain contribution. If he found a case where a hospital with paying beds had a deficit on its working he should in such circumstances only make a nominal charge. This would be an entirely new departure in Ireland. He would value paying beds on a much lower scale than he would value ordinary houses or shops.

The Marquis of BRISTOL gave evidence with regard to the claim for exemption made by the Eastern Counties Asylum for Idiots and Imbeciles, Colchester. He complained of the manner in which the assessment of the asylum had been raised by the local authority, and said he wished to see this institution and similar institutions exempted by Act of Parliament and not left at the mercy of local authorities. This being his view he did not think that a discretionary power vested in the local authorities would meet the case. He considered that such institutions should be free from the school rate and the poor rate, but that they might be called upon to contribute towards the district rate from which they derived some benefit.

Mr. JOHN J. C. TURNER, superintendent and secretary of the asylum, also gave evidence. He stated that institutions for the education, training, and care of idiots and imbeciles had been established by private benevolence and were really voluntary schools for imbecile children as well as homes for adult idiots. They were supported by voluntary contributions and were managed by committees of noblemen and gentlemen who gave their services gratuitously. These institutions were registered under Act 49 & 50 Vict., cap. 25, and existed for the benefit of the poorer classes whose imbecile children if not taken care of and educated therein would in many instances have to be supported out of the poor rates. Such institutions also received cases upon various rates of payment, and in four of these institutions cases were likewise received from boards of guardians upon payment at rates varying from 10*s.* 6*d.* a week. Any profit that might accrue either from private payment or boards of guardian cases went towards the support of free cases. The employés in these institutions, from the superintendent downwards, were all paid by salary, and were not in any way dependent on any profit that might be made from the reception of payment cases. Such institutions received no subsidy from the Treasury or any educational grant, and were heavily handicapped by having to pay local rates, especially school board and poor rates, from which they derived no benefit. Witness handed in the following table of figures with reference to the five institutions in England and the one in Scotland, viz.:—

Institution.	No. of beds.	Assessment.	School Board and poor-rates for 1899.	District rates for 1899.
Earlswood, Surrey	700	£2973	£166 6 8	£426 18 10
Royal Albert Asylum, Lancaster	640	1333	127 0 2	10 17 9
Eastern Counties Asylum, Colchester	235	600	129 17 3	91 16 2
Western Counties Asylum, Starcross	250	501	79 7 3	6 1 9
Midland Counties Asylum, Knowle...	72	216	23 15 3	11 16 8
Scottish National Institution, Larbert	280	508	56 9 4	85 13 11

Mr. HAYWARD, clerk to the Dartford Board of Guardians, was the last witness examined and gave evidence in corroboration of Sir William Hart Dyke. He stipulated that there should be no exemption unless there was local benefit.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADYE, WILLIAM JOHN ALEXANDER, M.R.C.S., L.S.A., has been appointed Medical Officer to the Bradford-on-Avon Workhouse by the Bradford-on-Avon (Gloucestershire) Board of Guardians.

BENNETT, JOHN, M.B., B.Ch. Irel., has been appointed Medical Officer for the Borough of Hyde, Cheshire.

CHILCOTT, E. S., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Itchen Urban District Council.

COOKSON, A. N., M.R.C.S., has been re-appointed Medical Officer of Health for the Nuneaton Sanitary District, Nuneaton Union.

DIXON, A., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Eighth Sanitary District of the Preston Union.

EMMETT, RICHARD, M.R.C.S., L.R.C.P., L.S.A., has been appointed Medical Officer to the Portsmouth Post Office, vice F. W. Way, retired.

FERGUSON, R. B., M.D. Camb., L R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the New Southgate District.

FLEMMING, CHARLES E. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the No. 1 District by the Bradford-on-Avon Board of Guardians.

FRASER, P., M.D. Edin., has been re-appointed Medical Officer of Health for Carnarvonshire.

GARNER, J. E., M.D. Aberd., has been re-appointed Medical Officer for the First Sanitary District of the Preston Union.

GILLETT, J. F., M.B., B.C. Camb., has been appointed Medical Officer for the Second Sanitary District of the Andover Union, vice L. W. Oliver, resigned.

GIMSON, K.C., M.B., B.C. Camb., has been appointed Medical Officer to the Urban District Council, Witham.

HAMILTON, D. L., L.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Timsbury Sanitary District of the Clutton Union, vice F. Woods, resigned.

HANNAH, E. W. ST. CLAIR, M.B., Ch.B. Aberd., has been appointed House Surgeon to the Kent County Ophthalmic Hospital, Maidstone, vice Percy E. Turner, resigned.

HARGREAVES, J. A., M.B., C.M. Aberd., has been re-appointed Medical Officer of Health by the Wetherby Rural District Council.

LEIGH, WILLIAM WATKIN, L.R.C.P., L.M. Edin., M.R.C.S., L.S.A., has been re-appointed Medical Officer for the Llanvabon District by the Pontypridd Board of Guardians.

LIMRICK, W. S., L.R.C.P., L R.C.S. Edin., has been re-appointed Medical Officer of Health for the Great Crosby Urban Sanitary District.

MACKEITH. J. M.B., C.M. Glasg., has been appointed Medical Officer to the Exeter Dispensary.

MARSHALL, C. DEVEREUX, F.R.C.S., has been appointed Assistant Surgeon to the Royal London Ophthalmic Hospital, City-road (Moorfields).

MOXON, HENRY J., L.D.S., R.C.S. Irel., has been appointed Dental Surgeon to the County Council's School at Feltham.

PICKARD, RANSOME, M.S., M.D. Lond., has been appointed Medical Officer to the Exeter Dispensary.

PLATT, J. E., M.S. Lond., F.R.C.S. Eng., M.D. Lond., has been appointed an Honorary Assistant Surgeon to the Royal Infirmary, Manchester, vice G. A. Wright.

SMITH, G. H., M.B., C.M. Aberd., has been appointed Medical Officer of the Workhouse, the Bucklow Union, vice T. J. Appleby, resigned.

THYNE, T., M.D. Edin., F.R.C.S. Eng., has been re-appointed Medical Officer for the Mill Corner and Cockfosters Sanitary District of the Parish of Enfield.

WRIGHT, G. A., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Royal Infirmary, Manchester, in succession to Thomas Jones, deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—Assistant House Surgeon. Salary £60 per annum, with apartments and board.

BRECON INFIRMARY, No. 6, Bulwark, Brecon, South Wales.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 per annum with board and residence.

BRISTOL EYE HOSPITAL.—Locum Tenens for the House Surgeon for two months. Salary 2½ guineas a week, without residence.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £120 per annum, with rooms and attendance (not board), or £80 per annum, with board.

CARDIFF INFIRMARY.—Assistant House Physician for six months. Salary at the rate of £75 per annum, with board, washing, and apartments.

CENTRAL LONDON SICK ASYLUM DISTRICT HOSPITAL, Cleveland-street, W.—Medical Officer as Locum Tenens. Salary £3 3*s.* weekly, with board, lodging, and washing.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Resident Medical Officer for twelve months. Salary £60 per annum. Also Registrar. Annual re-appointment, but tenable for three years. Honorarium 20 guineas per annum.

CHESTER GENERAL INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with residence and maintenance in the house.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

CORNWALL COUNTY ASYLUM, Bodmin.—Locum Tenens for one month or more. Terms £3 3*s.* and all found, with second class return fare.

CORPORATION OF BIRMINGHAM.—CITY HOSPITAL., Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer as Locum Tenens for a few weeks. Salary £3 3*s.* per week, with furnished apartments and board.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £80, with board, residence, and washing.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for six months. Salary £30 for that period, with board, residence, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon for twelve months. Salary of House Surgeon £100 per annum. Assistant House Surgeon £50, with furnished apartments, board, and washing in both cases.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

DURHAM COUNTY ASYLUM, Winterton, Ferryhill.—Junior Assistant Medical Officer. Salary £140, rising to £160 by annual increments of £10, with board, laundry, and attendance.

EAST SUFFOLK AND IPSWICH HOSPITAL, Thorofare, Ipswich.—Second House Surgeon for twelve months, unmarried. Salary £60, with board, lodging, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Senior House Physician for six months. Salary at the rate of £60 per annum, with board, lodging, and washing in the Hospital.

HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £100 per annum, rising £20 annually to £200, with board, lodging, washing, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Physician for six months, unmarried. Salary £20, with board and residence in the hospital.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

HULL CITY AND COUNTY LUNATIC ASYLUM.—Second Assistant Medical Officer at the Asylum, Willerby. Salary £120 per annum, rising £5 per annum to £150, with board, apartments, and washing. Applications to the Clerk to the Committee of Visitors, Town Hall, Hull.

LIVERPOOL DISPENSARIES, 34, Moorfields, Liverpool.—Four Assistant Surgeons, unmarried. Salary £100 per annum, with board and apartments.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £80, with board, lodging, and washing.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence in the Infirmary.

METROPOLITAN ASYLUMS BOARD.—Fourth Assistant Medical Officer at the Asylum at Darenth, near Dartford, Kent, unmarried. Salary £150 per annum, rising conditionally to £170, with board, lodging, attendance, and washing subject to statutory deduction. Apply to the Office of the Board, Victoria Embankment, London, E.C.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Soho-square, London.—Physician to Out-patients.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, N.E.—House Physician for six months. Salary at the rate of £80 per annum, with board, residence, and laundry. Also Resident Medical Officer for twelve months. Salary £120, with board, residence, and washing. Applications to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NORTH RIDING ASYLUM, Clifton, York.—Junior Assistant Medical Officer. Salary £125, with board, lodging, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—A Senior and a Junior House Surgeon for one year. Salary £100 and £75 per annum respectively, with board, residence, and washing.

PARISH OF BIRMINGHAM WORKHOUSE INFIRMARY.—Assistant Resident Medical Officer at the Workhouse Infirmary, for one year. Salary £100, with furnished apartments, rations (no alcoholic liquors), coals, gas, laundry, and attendance. Apply to the Clerk to the Guardians, Parish Offices, Edmund-street, Birmingham.

PECKHAM HOUSE ASYLUM, S.E.—Locum Tenens for two months.

PLYMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £125 per annum, with furnished apartments in the Asylum, board, and washing. Applications to the Clerk to the Visiting Committee, Municipal Buildings, Plymouth.

PONTEFRACT GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer, unmarried. Salary £150 per annum, with furnished rooms, fire, lights, and attendance.

ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried. Salary £90 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £50 per annum, with residence, board, and washing.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street, London.—House Surgeon and Registrar for six months, unmarried. Salary at the rate of £100 per annum, with residence and partial board.

RUBERY-HILL ASYLUM FOR THE CITY OF BIRMINGHAM, Barnt-green, Worcestershire.—Senior Assistant Medical Officer.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary at the rate of £80 per annum, with board, residence, laundry, &c.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, London.—Demonstrator of Physiology. Salary £150.

ST. MUNGO'S COLLEGE, GLASGOW, FACULTY OF MEDICINE.—Bellahouston Chair of Anatomy. Emoluments £300 per annum.

SALOP INFIRMARY, Shrewsbury.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board and washing.

SCARBOROUGH HOSPITAL AND DISPENSARY.—House Surgeon for twelve months. Salary £90, with residence, board, and washing. Also Assistant House Surgeon for six months. Salary at the rate of £75, with residence, board, and washing.

STAMFORD-HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington.—Assistant Resident Medical Officer. Salary £100 per annum, with board.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician for twelve months. Salary £50 per annum, with board, apartments, washing, and attendance.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing. In lieu of stimulants or mineral waters £6 per annum will be given.

THE CHIEF INSPECTOR OF FACTORIES gives notice of a vacancy of Certifying Surgeon under the Factory Acts at Saddleworth in the West Riding of the County of York.

UNIVERSITY COLLEGE, Cardiff.—Demonstrator and Assistant Lecturer in Anatomy, and Demonstrator and Assistant Lecturer in Physiology. Salary in each case, £120,

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £75 per annum, with board, residence, &c.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House Surgeon. Salary £80, rising £10 annually to £100, with board, residence, and washing.

WILTS COUNTY ASYLUM, Devizes.—Assistant Medical Officer, unmarried. Salary £130, rising £10 a year (if approved) to £160, with board (no beer or wine), residence, attendance, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Surgeon, for six months. Honorarium at the rate of £75 per annum, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance

Births, Marriages, and Deaths.

BIRTHS.

BUCKLEY.—On June 27th, at Gillott-road, Edgbaston, Birmingham, the wife of J. R. Buckley, M.B. Lond., M.R.C.S., of a son.

CUTTING.—On June 28th, at Chetwynd House, Stalham, Norfolk, the wife of Ernest Buxton Cutting, M.R.C.S., L.R.C.P., of a son.

DEAN.—On June 24th, at Queen-street, Lancaster, the wife of Charles William Dean, F.R.C.S.E., of a daughter.

DOUGLAS.—On June 28th, the wife of A. R. Douglas, L.R.C.P., L.R.C.S., Resident Medical Officer Royal Albert Asylum, Lancaster, of a son.

GLOVER.—On June 27th, at 17, Belsize-park, Hampstead, the wife of Lewis G. Glover, M.D., of a daughter.

HARDING.—On June 22nd, at Whittlesea, Cambs, the wife of C. H. Harding, M.R.C.S., L.R.C.P. Lond., of a son.

HUTCHINSON.—On July 1st, at Loneside, Haslemere, Surrey, the wife of R. J. Hutchinson, M.R.C.S., L.R.C.P., of a daughter.

JACKSON.—On July 1st, at Grove Lodge, Winchmore-hill, Middlesex, the wife of John W. Jackson, L.R.C.P., M.R.C.S., of a daughter.

MORETON.—On June 28th, at Dunsley, Cotham-park, Bristol, the wife of T. W. E. Moreton, B.A. Cantab., M.R.C.S., L.R.C.P., of Tarvin, Chester, of a son.

NEWBOLT.—July 2nd, at 42, Catharine-street, Liverpool, the wife of George Palmerston Newbolt, M.B., F.R.C.S., of a daughter.

MARRIAGES.

ARNOTT—HEWLETT.—On June 27th, at St. George's (Parish) Church, Beckenham, by the Rev. Henry Arnott, F.R.C.S. Eng., rector (father of the bridegroom), assisted by the Rev. Chas. Green, vicar of St. Paul's, New Beckenham, Neil, eldest son of the Rev. H. Arnott, to Evelyn Mary, eldest daughter of John C. Hewlett, Esq., F.C.S., of Hillside House, Beckenham, Kent, and 40, 41, and 42, Charlotte-street, London, E.C.

ROUNTREE—VAILE.—On June 30th, at St. Peter's, Belsize-park, William Augustine Rountree, M.B., B.Ch., of Haverstock-hill, to Mary Collett (Collie), eldest daughter of T. H. Vaile, of Belsize Park-gardens, Hampstead.

TUKE—FRASER.—At the Roxburghe Hotel, Edinburgh, on 27th June, by the Very Rev. Archibald Scott, D.D., St. George's, and the Rev. Robert Stevenson, M.A., Dunfermline Abbey, Alan L. S. Tuke, M.B., C.M., youngest son of Sir John Batty Tuke, M.P., to Dorothy, only surviving child of the late William Fraser, Inverkeithing, Fife.

DEATHS.

GOULD.—At Whiteknight's Park, Reading, on July 1st, after a very short illness, Catherine Alfreda, the eldest and dearly loved daughter of Alfred Pearce Gould, of 10, Queen Anne-street, London, aged 20.

EWBANK.—On July 2nd, at 5, Berkeley-place, Cheltenham, Henry Ewbank, M.R.C.S., aged 44 years.

LEECH.—On July 2nd, at his residence, Elm House, Whalley Range, in his 61st year, Daniel John Leech, M.D., D.Sc., F.R.C.P., Professor of Materia Medica and Therapeutics in the Owens College, Manchester.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HONOUR AND DIGNITY OF THE MEDICAL PROFESSION.

A CORRESPONDENT writes:—"Notwithstanding the increasing age of the candidates for the medical profession, the increased cost of their education, and the length of time required to obtain a legal qualification, are we really at bottom—socially, professionally, and otherwise—superior to our predecessors in the healing art? There has been far too much nonsense preached at the annual introductory lectures at our medical schools—that we should 'look for our reward hereafter'; that we should 'retrace our steps at the very threshold if we are seeking pecuniary reward,' &c., &c., *ad nauseam*. But after all is said and done, what is a man in any profession or calling, including medicine and even the Church, valued at if he is poor? Is the money, honourably earned, no test whatever of success? Has not many a brilliant man gone down into a pauper's grave? Does anyone shed a tear of regret for the poor, dead or living? Possibly a few may do so, but their tears can be counted and they do not often scald.

"The recent revelations respecting the lunacy scandals in the parish of St. Pancras may come as a surprise, and possibly as a grief, to some. But the foul ulcer is not a new one; it is chronic—shall I say 'spreading'?—for the same scandal has existed for over 30 years in more than one parish in this metropolis to my own certain knowledge, and how many years previously I will not venture to suggest. The entire subject is a most unsavoury one, but it is best not to attempt to hide it or hush it up lest worse befall us and we as a profession have to pass through the same painful portals that another profession—that of the law—is passing through at the present time. It is time carefully to inquire into the management of our own happy home and also into the conduct of some of our own more unworthy brethren ere the bud becomes the decayed and drooping flower. Surely, there should be some kind of court of preliminary inquiry into the conduct and bearing of certain members of our profession before the serious question arises of removing a name from the Medical Register.

"It is not always the poor man who is to blame, but frequently it is the one who ought to be able to keep up the honour and dignity of the profession and who does know better who is the greater offender. True nobility is not a monopoly of the rich. The sharing of fees with relieving officers, the keepers of licensed establishment for the reception of lunatics, drunkards, &c., coroners' officers, policemen, and nurses is not a very dignified or desirable position for a medical man. Even coroners' officers are painted with the same brush; and some time ago one of these men had the audacity to offer me only a part of my legal fee, and at the same time made the excuse that Dr. So-and-So always allowed a discount of 25 per cent. Was this bribe given in order to secure the officer sending cases to this particular doctor? If so the donor was singularly unfortunate as he was only opening the door to bribery, corruption, and public scandal. I once knew of a nurse who retained 5*s.* from a fee of 5 guineas handed to her to be given to a doctor for attending a lady in her confinement. The doctor, who was one of the old school, said nothing to the nurse, but returned at once to the patient and inquired whether she had not made a mistake of 5*s.* in his fee. Again, to come to more recent times, since the General Medical Council have made some weak pronouncement respecting medical men attending certain medical aid societies I know of cases of medical men living in large houses and driving their own carriages who have resigned a few of their more doubtful appointments as medical officers to medical aid societies and the like, fearing the possibility of their conduct reaching the ears of the General Medical Council. This fear is most wholesome, for most offenders of this class are arrant cowards, but at the same time some of these nervous ones have conveyed to the rejected clubites that 'quite privately, you know, I shall be pleased to see you at my surgery for one shilling.' I should like to know why little children such as 'Juvenile Foresters,' 'Juvenile Oddfellows,' and the like should be attended for half the usual fees, such as 6*d.* a quarter and even less? Is the life of a little child only of half the value of that of the parent? Is the time or skill, or even the medicine, of less value than that which is doled out to the parents. I have known the case of two little children living under the same roof and belonging to the same parents one of whom was a Juvenile Forester and the other a Juvenile Oddfellow, and these two little mites have been receiving the distinguished attention of two doubly qualified physicians and surgeons of our Royal Colleges, who have been only too delighted to drive up to their humble cottage with horse and carriage, coachman, cockade, and fur cape and cuffs included, and all for one halfpenny a week. There was a time when we never received less than 1*d.* Need anyone be surprised how these little children will respect us in the years to come.

"Take the case of life-insurance offices. There was a time when no medical man of repute would take a fee of less than one guinea for

examining the life of an insurer, but now that industrial offices accept lives for small sums of insurance these offices plead that they cannot pay such large fees, and in this way our position is assailed and our fees are cut down and undermined. Is the time required of less value when examining the poor? Is there less need of care on our part? Is the fee so small that there is no longer any need for us jealously to defend our written diagnosis, no longer any necessity to defend the honour and dignity of the profession? We really have only ourselves to thank for this gradual, but certain undermining, of our nobility. If the lives of the poor are to be insured, by all means let them be so, but not at the expense of the medical profession. Let these offices take such small sums and lives at their own risk, or else pay some of the enormous funds which are at their disposal to some of our poorer brethren who are trying so hard to keep the wolf from the door, but who frequently find themselves quite unable to do so in consequence of the mean trade-like competition within our ranks."

A GOOD BICYCLE SADDLE.

To the Editors of THE LANCET.

SIRS,—Can you or any of your correspondents tell me the name of a good anatomical saddle for a bicycle where a proper support is given to the buttocks of a rider in the upright (non-stooping) position and where at the same time the thighs are not apt to get chafed?

I am, Sirs, yours faithfully,

June 25th, 1900. B.

SOME OF THE FACTORS LEADING TO A RELATIVELY HIGH PERCENTAGE OF MALE OFFSPRING.

To the Editors of THE LANCET.

SIRS,—After studying more than 300 marriages with the object of discovering some of the conditions likely to give rise to a relatively high percentage of boys I have come to some conclusions which I now give for what they are worth. Possibly some of your readers may have time and opportunity to work out a still larger number of cases and to compare their results with mine. It seems to me that this should not be regarded as a mere matter for curiosity, but as having real practical bearings. I think that if my rules are followed we shall hear less often the complaint of paterfamilias that he has "seven daughters who prophesy" and, alas, not one boy! The conditions thrown into rules are:—1. Do not marry the eldest daughter of a family but rather the youngest. There is a progressive increase of boy-producing power from the eldest up to the youngest daughter. 2. Do not marry one whose age differs much from your own; and do not marry much under or over 30. 3. Do not marry a widow. 4. Do not refuse to marry a cousin or an only daughter. No doubt there are other factors to be taken into account, but here I think we have some rather important ones. I am, Sirs, yours faithfully,

Sutton, June 29th, 1900. GERALD S. WALTON, M.B., C.M. Edin.

AN APPEAL TO BROTHER PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers suggest a line of treatment likely to be of use to me? For the last few months I have at times suffered from rheumatism in my right hip-joint, aggravated by long walks or damp weather. I am 59 years old, very temperate, always had good health, weight 14 stone, urine normal. Being fond of shooting I do not want to become an arthritic cripple. Would cider be harmful? I have given it in cases of atonic gout with great benefit.

I am, Sirs, your faithfully,

July 3rd 1900 M.D.

THE TREATMENT OF MORPHINOMANIA.

To the Editors of THE LANCET.

SIRS,—A lay paper recently published a statement that Dr. O. Emmerich of Baden-Baden had discovered a drug useful in morphinomania. Can you or your readers give me any information or refer me to papers written by him?

I am, Sirs, yours faithfully,

ROGER N. GOODMAN, M.D. Cantab.

Kingston-on-Thames, July 1st, 1900.

SHAM DIPLOMAS IN THE UNITED STATES.

WE are accustomed from time to time to see accounts of inquests held upon the bodies of those who have died while under the care of quacks who pose as "qualified" and put after their names such letters as F.C.S.M. or M.B., the latter letters signifying not Medicinæ Baccalaureus but Medical Botanist. This, of course, is the explanation given by the quack. Only, naturally enough, his dupes think the letters refer to the genuine degree and naturally, also, that is what the quack counts upon. In the United States, however, the sham diploma factory flourishes to a greater extent than here, and we rejoice to see that a raid has at length been made upon such an institution which had its local habitation in Chicago. Its late title is the Metropolitan Medical College, and its history, according to the *Chicago Daily Tribune*, is as follows:—The institution was organised in 1895 under the name of the Illinois Health University. The charter for this name was revoked by the board two years later. Immediately the college was re-organised by the same owners under the name of the Independent Medical College. A revocation of this charter in December last resulted in the college being started anew under the name of the Metropolitan Medical College. Finding that the promoters of the institution had seven charters remaining under which the institution could be conducted, Attorney John A. Barnes, counsel for the board, interested the Post-office authorities in the prosecution. The charge upon which the proprietors have been arrested is that of using the mails to defraud. They sold worthless diplomas through the post for sums varying from 25 dollars to 100 dollars, and some of the victims gave evidence in the police-court. We are afraid that a charge of "using the mails to defraud" would not stand on this side of the Atlantic, but if only it could be made to do so there might be some chance of many thieves being brought to book. To say nothing of the innumerable prospectuses of bubble companies there are the circulars of the "Free portrait" swindlers, of quacks such as "Dr." Bell, and the specious promises of the money-lending fraternity. The number of fools is incalculable, but the swindler with brains should not be assisted by the Government in his nefarious trade.

"THE CASE OF THE LATE MR. ALFRED BOURNE."

To the Editors of THE LANCET.

SIRS,—The following is the third list of subscriptions.

I am, Sirs, yours faithfully,

Northallerton, June 26th, 1900. J. A. HUTCHINSON.

	£	s.	d.
Rev. R. J. Steele (Harlsey)	1	0	0
Mrs. Jefferson (Northallerton)	0	10	0
Miss J. Yeoman (Northallerton)	1	0	0

THE OPEN-AIR TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me where a servant girl can be treated for early phthisis by the open-air method? Her mistress will pay a reasonable figure weekly for her.

I am, Sirs, yours faithfully,

July 3rd, 1900. J. B.

*** A list of institutions was given in THE LANCET of Sept. 9th (p. 724) and 23rd (p. 851), 1899.—ED. L.

"PULEX IRRITANS."

To the Editors of THE LANCET.

SIRS,—If "C. M. H." will freely spread dry chloride of lime on the floors and then order the floors to be washed with the scrubbing-brush in the ordinary way, he will not only whiten the floors, but will also completely rout the enemy, which will not, like De Wet, renew the attack. I am, Sirs, yours faithfully,

Holland Park Avenue, W., July 4th, 1900. ALFRED E. BARRETT.

Pathology.—Full information with regard to post-graduate study in foreign universities will be found in the Students' Number of THE LANCET for 1899. Foreign degrees are as a rule granted to medical men holding English qualifications only after they have gone through the full foreign curriculum. Some of the foreign universities admit the use of interpreters, but, practically speaking, a knowledge of the language is—and we think should be—essential. Some of the university towns are much more economical to live in than others, but the allowance is a larger one than the foreign student enjoys as a rule. If our correspondent can live as a native he will be well off, but to do this he must have a working knowledge of the language.

Expectant.—There is no rule. The purchaser, we think, generally pays, but the matter is one for mutual arrangement between the parties.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Stalybridge Herald, Sporting and Dramatic News (London), Bullionist, South Wales Daily News, Birmingham Daily Post, Liverpool Daily Post, Jersey Express, East Anglian Daily Times, Newcastle Daily Chronicle, Manchester Guardian, Glasgow Herald, Cornishman, Leeds Mercury, Nottingham Daily Guardian, Birkenhead News, Cheltenham Mercury, Times of India, Pioneer Mail, Architect, Builder, Citizen, Scotsman, Bristol Mercury, Yorkshire Post, Brighton Gazette, Sanitary Record, Medical Review, Madras Standard, Modern Society, Chester Courant, Newbury Weekly News, City Press, Lincolnshire Chronicle, Reading Mercury, Oban*

Times, Jewish Chronicle, Hertfordshire Mercury, Local Government Journal, Surrey Advertiser, Surrey Gazette, Hereford Mercury, Weekly Free Press and Aberdeen Herald, Wiltshire Times, Worcester Herald, Suffolk Chronicle, Peterborough Express, Keighley Herald, Dover Standard, Gloucester Journal, Manchester Courier, Admiralty and Horse Guards Gazette, People (London), Bolton Journal, New Age (London), Kent County Examiner, &c., &c.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Willcocks: Medical Cases. (Post-graduate Course.)

FRIDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. Tilley: Consultation. (Nose and Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—A. E. P.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address
ON
THE IMPORTANCE OF POST-GRADUATE STUDY.

Delivered at the Opening of the Museums of the Medical Graduates' College and Polyclinic on July 4th, 1900,

BY WILLIAM OSLER, M.D., F.R.S.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE, U.S.A.

MR. PRESIDENT AND GENTLEMEN,—If the licence to practise meant the completion of his education how sad it would be for the practitioner, how distressing to his patients! More clearly than any other the physician should illustrate the truth of Plato's saying that education is a life-long process. The training of the medical school gives a man his direction, points him the way and furnishes a chart, fairly incomplete, for the voyage, but nothing more. Post-graduation study has always been a characteristic feature of our profession. These 300 years the schools of Italy, Holland, France, Austria, and Germany have in turn furnished instruction to the young English practitioners who believed in the catholicity of medicine and who felt the sharp sting of the remark which associates homely wits with home-keeping youths. At first it was the grand tour, and many of the masters spent years in foreign study. In spite of our journals and international societies and increased facilities for travel I am not sure that among the teachers in our art the world over medicine to-day is more cosmopolitan than it was in the seventeenth and eighteenth centuries. We now spend a few months or a year in foreign study, whereas our great-grandfathers thought nothing of two and three years. I have seen the MSS. Journal of Dr. John Morgan (a Pennsylvania colonist), the founder of the first medical school in America (University of Pennsylvania), who, after graduation at Edinburgh, spent three years on the continent and became thoroughly familiar with Italian, Dutch, and French medicine, reaching such distinction as a student that he took his seat as a corresponding member of the Paris Academy of Surgery and was elected a Fellow of the Royal Society. Linacre, Caius, and Harvey remain to-day the models for all students in foreign lands, but the pace they set is a hard one to keep up. In the rapid extension of methods and subjects in medical education during the past quarter of a century post-graduate teaching has come in for a full share of attention. In the United States many special schools have been organised and perhaps more systematic attention has been paid to the subject than anywhere except in Germany. In New York, in Philadelphia, and in Chicago, the polyclinics and post-graduate colleges have been widely appreciated by practitioners and have done much good. Less successful attempts have been made by some of the ordinary medical schools, but the leading ones have now abandoned in great part the teaching of graduates. Personally, I have been engaged in the work for the past 11 years. For the first five years of the organisation of the Johns Hopkins Hospital we admitted only physicians, but since the medical school proper began we have had courses for graduates in the months of May and June. At any time during the year, at the discretion of the professor, a few special students may enter the classes or work in the laboratories. So far as the subject of medicine is concerned it is easy to arrange very attractive courses in routine ward instruction, in physical diagnosis, and in clinical micropsy. I have just finished a six weeks' course of clinical instruction to a class of about 30 general practitioners, and to meet these good earnest students from all parts of the country, some of whom have been in practice 15 or 20 years, stimulates one's optimism as to the outlook in the profession.

Upon the advantage which London offers for graduate study it would be superfluous to dwell, since here is collected a larger number of sick people than in any city in the world. The special hospitals offer unequalled facilities for the study of diseases of the eye, of the skin, of the nervous system, and of the diseases peculiar to women and to children. The absence of concentration of material so convenient in Vienna is counterbalanced by the much more elaborate equipment to be found in the special hospitals. There has been but one thing lacking—the organisation necessary to bring patients and students into intimate association, for which purpose this college for graduates was started. Until recently the physician who came to London felt lost and perplexed, and even if he took out three or four hospital tickets there was but little systematic teaching and he had to pick up information as best he could. Here he finds a local habitation with a comfortable reading-room, a good library, and a well-arranged curriculum embracing all the practical branches of medicine and surgery.

The value of a Museum as a means of practical instruction was first practically demonstrated by John Hunter whose magnificent collection is in itself a college for graduates. So extensive is the material, so admirably arranged, and so well catalogued that to the general practitioner and to the special student it offers a unique field for study. I am surprised that a larger number of physicians do not take advantage of the opportunity there offered to study accurately and systematically the manifold manifestations of disease. To Hunter's example is owing the place which the museum occupies in the medical schools of this country. You have been fortunate in having associated with your College a man with a truly Hunterian mind. In the broad scope of his work, in the untiring zeal with which he has studied the natural phenomena of disease, in his love for specimens and collections, Mr. Jonathan Hutchinson, bears a strong likeness to the immortal Hunter. No individual contributor in this country has made so many careful observations upon so many diseases. He is the only great generalised specialist which the profession has produced, and his works are a storehouse upon which the surgeon, the physician, the neurologist, the dermatologist, and other specialists freely draw. When anything turns up which is anomalous or peculiar, anything upon which the text-books are silent and the systems and cyclopædias are dumb, I tell my students to turn to the volumes of Mr. Hutchinson's "Archives of Surgery," as if it is not mentioned in them we surely have something very much out of the common. It is very fortunate that the collection which he has made will be kept together, as it will be of great service to students from all parts of the world. In one respect it is unique, pictorial and clinical, not anatomical and pathological, and it will remain a worthy monument to the zeal and perseverance of a remarkable man, a man who has secured the homage of a larger number of clinical workers than any Englishman of his generation.

Post-graduate instruction is needed in all classes among us. The school for the young practitioner is a general practice in which the number and variety of cases will enable him at once to put his methods into daily use. A serious defect may warp his course from the outset. Our students study too much under the one set of teachers. In English and American schools they do not move about enough. At a tender age, four or five years give a man a sense of local attachment to place and teachers which is very natural, very nice, but not always the best thing for him. He goes out with a strong bias already in his mind and is ready to cry "I am of Guy's," "I am of Bart's," or "I am an Edinburgh man." To escape from these local trammels, which may badly handicap a man by giving him an arrogant sense of superiority often most manifest when there is least warrant, is very difficult. I knew three brothers, Edinburgh men, good fellows at heart and good practitioners, but for them the science and art of medicine never extended beyond what their old teachers had taught. A Guy's man they could just endure, for the sake, as one of them said, of Bright and Cooper and Addison, but for men of other schools they entertained a supreme and really ludicrous contempt.

There are two great types of practitioners—the routinist and the rationalist—neither common in the pure form. Into the clutches of the demon routine the majority of us ultimately come. The mind, like the body, falls only too readily into the rut of oft-repeated experiences. One evening in the far North-West, beneath the shadows of the Rocky Mountains we camped beside a small lake from which diverging in all directions were deep furrows, each one as straight as an arrow, as far as the eye could reach. They were the deep ruts or tracks which

countless generations of buffaloes had worn in the prairie as they followed each other to and from the water. In our minds countless, oft-repeated experiences wear similar ruts in which we find it is easiest to travel, and out of which many of us never dream of straying. Year by year we follow the same plan in practice, give the same drugs, and settle down into routinists of a most commonplace type. Last year I was called to a town in Pennsylvania and having to wait until late in the evening for the return train, I insisted, as is my wont, that the medical man should carry on his daily work and allow me to help him if possible. An afternoon round among patients chiefly of the mechanic class showed me a shrewd cheery man who in 20 years had gained the confidence and esteem of his patients. Kindly, hopeful words, very sensible directions about diet, and some half-dozen drugs, seemed the essential in his practice. In the evening I saw him dispose of a dozen patients at an out-door dispensary rate; the examination was limited to the pulse, the tongue, and sometimes the throat. The dispensing, which was of the most primitive sort, was done at the table, on which stood four or five tin and paper boxes containing large quantities of calomel, soda, antipyrin, and Dover's powder. Other drugs, he said, were rarely necessary. He never used a stethoscope, he had no microscope or instruments of precision other than the thermometer. In reply to my questions he said "that he rarely had to make an examination. If the patient has fever I send him to bed, if there is œdema I ask for the urine. Of course, I make many mistakes and I sometimes get caught, but not oftener than the other fellows, and when I am in serious doubt I ask for a consultation." This was a man of parts, a graduate from a good school, but early in his career he had become very busy, and gaining the confidence of the people and having much confidence in himself he had unconsciously got into a rut, out of which at 40 only one thing could lift him—a prolonged course of additional study. This is by no means an exaggerated picture of a routinist in general practice. We all have our therapeutic ruts and we all know consultants from whom patients find it very difficult to escape without their favourite prescription, no matter what the malady may be. Men of this stamp gain a certain measure of experience, and if of a practical turn may become experts in mechanical procedures, but to experience in the true sense of the word they never attain. In reality they suffer with the all-prevailing vice of intellectual idleness. It is so much easier to do a penny-in-the-slot sort of practice, in which each symptom is at once met by its appropriate drug than to make a careful examination and really to study the case systematically. Much depends on a man's mental constitution, but much more on the sort of training he has had. If when a student good methods are not acquired it is very hard to get into proper habits of work in practice.

The rationalist, on the other hand, always approaches a patient as a mathematician does a problem. There is something to be found out; in each case, however trivial, there is something novel, and the problems of causation and the question of relief, while not perhaps of equal importance, are of equal interest. He may be just as busy as his idle brother, but he finds time to keep up a technical dexterity in the use of instruments of precision and the stethoscope and the microscope are daily helps in diagnosis. These men are the delight of the consultant. To go into the country and find the diagnosis made in a case of mitral stenosis, a Friedrich's ataxia, a case of leukæmia, or one of myxœdema gives a man a thrill of pleasure such as Comte says he always felt when a student gave him an intelligent set of answers in an examination. It is this class of practitioners for whom the post-graduate courses are helpful and necessary. They alone feel the need of keeping abreast with the times, and men of this type will return every few years, finding that a three months' course of study not only improves and helps them personally but is most beneficial in their practices.

The members of no class in our ranks travel to the waters in deeper or straighter ruts than the specialists. To work for years at diseases of the skin, ophthalmology, gynæcology, &c., necessarily tends to make a man narrow not only as a practitioner but in other relations. One of the best features of British medicine has been the practice of specialties by general surgeons and physicians. It has been better for the men themselves perhaps than for the patients and for the particular branch practised. Nowadays, to master even the smallest specialty requires concentrated effort of years' duration, and to counteract the benumbing influence of isolation a man must scan the wide horizon of pathology and must cultivate ardently the general interests of his profession. The degree of advancement of the specialties in different countries must be borne in mind by our friends and there are few who have been in practice for five or ten years who would not be benefited by a course of study in some foreign country.

After all, no men among us need refreshment and renovation more frequently than those who occupy positions in our schools of learning. Upon none does intellectual staleness steal "with velvet step, unheeded, softly," but not the less relentlessly. Dogmatic to a greater or less degree all successful teaching must be, but year by year, unless watchful, this very dogmatism may react upon the teacher who finds it so much easier to say to-day what he said last year. After a decade he may find it less trouble to draw on home supplies than to go into the open market for wares, perhaps not a whit better, but just a wee bit fresher. After 20 years the new even when true startles, too often repels; after 30, well, he may be out of the race, still on the track perhaps, even running hard, but quite unconscious that the colts have long passed the winning post. These unrefreshed, unregenerate teachers are often powerful instruments of harm and time and again have spread the blight of a blind conservatism in the profession. Safely enthroned in assured positions, men of strong and ardent convictions, with faithful friends and still more faithful students, they too often come within the scathing condemnation of the blind leaders of the blind, of those who would neither themselves enter into the possession of new knowledge nor suffer those who would to enter. The profession has suffered so sorely from this blight of intellectual old fogeyism that I may refer to the most glaring instances in our history. In the scientific annals of this great metropolis there is no occasion more memorable than April 16th, 1616, when Harvey began his revolutionary teaching. Why the long, the more than Horatian delay in publishing his great discovery? He knew his day and generation and even after 12 years of demonstration, which should have disarmed all opposition, we know how coldly the discovery was received, particularly in certain quarters. Harvey, indeed, is reported to have said that he did not think any man above 40 years of age had accepted the new truth. Many of us have lived through and taken part in two other great struggles. The din of battle over the germ theory of disease still rings in our ears. Koch's brilliant demonstration of the tubercle bacillus had a hard up-hill fight to recognition. The vested interests of many minds were naturally against it, and it was only the watchers among us, men like Austin Flint, who were awake when the dawn appeared. It is notorious that the great principles of antiseptic surgery have grown slowly to acceptance, and nowhere more slowly than in the country in which they were announced, the country which has the great honour to claim Lord Lister as a citizen. Old fogeyism of the most malignant type stood in the way, and in some places, strange to say, still stands. Mentally it is possible that surgeons age earlier than physicians. I remember as a student, listening to the introductory lecture of a distinguished surgeon at one of the metropolitan schools the burden of whose discourse was the finality which had been reached by modern surgery. In boldness of conception and in precision of execution, he said, we could scarcely hope to see any further progress. Poor man! Cerebral, renal, and hepatic surgery, to say nothing of other operative advances, followed in rapid succession, and I only quote this as illustrating the state of mental blindness with which we teachers may be smitten.

As Locke says: "Truth scarce ever yet carried it by vote anywhere at its first appearance," and these well-known examples illustrate a law in human knowledge that a truth has to grow to acceptance with the generation in which it is announced. Progress is an outcome of a never-ending struggle of the third and fourth decades against the fifth, sixth, and seventh. Men above 40 are rarely pioneers, rarely the creators in science or in literature. The work of the world has been done by men who had not reached *la crise de quarante ans*. And in our profession wipe out, with but few exceptions, the contributions of men above this age and we remain essentially as we are. Once across this line we teachers and consultants are in constant need of post-graduate study as an antidote against premature

senility. Daily contact with the bright young minds of our associates and assistants, the mental friction of medical societies, and travel are important aids. Would you know the signs by which in man or institution you may recognise old fogeyism? They are three: First, a state of blissful happiness and contentment with things as they are; secondly, a supreme conviction that the condition of other people and other institutions is one of pitiable inferiority; and thirdly, a fear of change, which not alone perplexes but appals.

Conservatism and old fogeyism are totally different things; the motto of the one is "Prove all things and hold fast that which is good," and of the other "Prove nothing but hold fast that which is old." Do not suppose that you have here a monopoly of the article, which is a human, not a national, malady, for we see a very virulent type in America. In its illusiveness and in the disastrous consequences which have often followed its hunting, old fogeyism is a sort of Snark in the medical profession. Before the Boojum, in the form of an entrenched variety, many good men and true have softly and silently vanished away like the beamish nephew of the bellman, sacrificed to intellectual staleness in high places. One of the best correctives is the plan followed at Harvard which compels (?) every teacher to take the Sabbatical year, ensuring in this way rest of the mind if not refreshment. To maintain mental freshness and plasticity requires incessant vigilance; too often, like the dial's hand, it steals from its figure with no pace perceived except by one's friends and they never refer to it. A deep and enduring interest in the manifold problems of medicine and a human interest in the affairs of our brotherhood—if these do not suffice nothing will.

As I stated at the outset, during the past three centuries English students have frequented in turn different countries, drinking deep, deep draughts at the great fountains of learning. Think of the debt we owe to these men and to their foreign masters! Linacre and his successors. Caius, Harvey, and Glisson, brought the new learning from Italy and, moreover, gave to English medicine that smack of culture, that tincture so peculiarly its own. From Holland a succeeding generation drew rich stores of knowledge, and the methods of teaching of the great Boerhaave were quickly adopted by English and by Scotch students. From France came next the new science of Bichat, the new art of Laennec, and the new methods of Louis. To another group the great teachers of Austria contributed accuracy in clinical methods, a zest for the study of special branches and a much-needed, at the time, therapeutic nihilism. The debt of the present generation to Germany can never be paid. Think of the scores who have found inspiration in our common master Virchow; and in the scientific study of disease the Fatherland is still in the van. The great Republic of Medicine knows and has known no national boundaries, and post-graduate study in other lands gives that broad mental outlook and that freedom from the trammels of local prejudice which have ever characterised the true physician.

The course of Empire has opened new fields in which problems new and old have been presented for solution, some of which are of great interest to you "on this side of the water." In any comprehensive survey of the educational field in medicine perhaps the most important single event during the past quarter of a century has been the silent revolution which has taken place in the United States, a revolution which has a direct bearing upon the matter in hand. Everywhere in the schools the entrance requirements have been strengthened, the course of study has been prolonged, and the character of the examinations changed. The hospital equipment has been enormously improved and the clinical facilities have been correspondingly increased. But a still more striking change has been the cultivation of the scientific branches of medicine. 25 years ago physiological laboratories were few and far between; now the output of a score of well-established laboratories supports one of the best journals of physiology in the world. The study of pathology has shown a corresponding growth. The most hopeful feature is a restless discontent which, let us hope, may not be allayed until the revolution is complete in all respects. Meanwhile, to students who wish to have the best that the world offers, let me suggest that the lines of intellectual progress are veering strongly to the West, and I predict that in the twentieth century the young English physicians will find their keenest inspiration in the land of the setting sun.

The Ingleby Lectures

ON

THE COMMONER NEUROSES OF CHILDHOOD, THEIR PATHOLOGY AND TREATMENT.

Delivered at the Mason University College, Birmingham, on June 27th and July 4th, 1900,

BY O J. KAUFFMANN, M.D., M.R.C.P. LOND.,
PHYSICIAN TO QUEEN'S HOSPITAL, BIRMINGHAM; LATELY PROFESSOR OF PATHOLOGY, MASON UNIVERSITY COLLEGE, BIRMINGHAM.

LECTURE II.[1]

Delivered on July 4th.

MR. DEAN AND GENTLEMEN,—Migraine and recurrent paroxysmal headaches which are deficient in the special characteristics that distinguish migraine are common in children, the latter type being particularly frequent. It would be an error to attempt a sharp separation between these two affections, for although the characteristics which mark migraine—viz., the sensory symptoms, the unilateral commencement of the pain, and the sickness and vomiting—are very prominent, yet we find that typical attacks of hemicrania alternate with simple non-migrainous headaches, and that one form may, in any individual sufferer, replace the other in the course of time. Moreover, the vaso-motor symptoms and the fluctuations in the blood pressure which in typical migraine are so pronounced are seldom, if ever, quite absent from recurrent headaches of the simple kind. Precisely the same causes are found to produce both these forms of cephalalgia.

The true character of these headaches is shown by their recurrent character, a slight cause sufficing, in those who are predisposed, to bring on a paroxysm; and it follows that in dealing with cases of this kind we must attack the predisposing factors, if they be accessible to treatment. In the opposite event we must content ourselves with recognising those causes which immediately excite the attacks and instructing the patient to avoid them. Children suffering from this complaint usually show evidence, even in the intervals between the attacks, of being out of health, but in exceptional instances they appear to be in good physical condition. Without going into great detail, the causes which lead to migraine may be stated thus: 1. Heredity, direct or indirect. 2. Overwork, mental or physical. 3. Overstrain of the eyes. 4. Slight injuries. 5. Metallic intoxication, tobacco intoxication, and alcoholic intoxication. 6. Depressed general health arising from either (1) previous disease, (2) respiratory intoxication, (3) disorders of the alimentary tract, or (4) unsuitable diet. 7. Indigestion and constipation without evident impairment of the general health. It will be at once seen that no definite line severs the predisposing from the exciting causes; for in an individual who is led to the verge of migraine by, say, overwork at school a slight extra amount of work will precipitate an attack.

Now, if we consider the toxæmic conditions which predispose to these headaches we are struck by the prevalence of those which arise from unsuitable diet or from other disorders of the alimentary canal. Very often one can elicit a history of constipation, and this or an account of irregularity of the bowels will generally direct us straight to the cause of the trouble. Then we shall on inquiry often be confronted with an account of most unsuitable feeding; the child either has its meals irregularly or they consist of materials quite unfit for its consumption, and very usually the diet is faulty in both these particulars. Even a short experience will convince any observer that in these two conditions, constipation and faulty feeding, are founded a large number of cases of migraine. There may be, on the other hand, a state of catarrh of the gastro-intestinal tract which is not due to errors of diet or constipation, but which results from infective disease. Measles and whooping-cough

[1] Lecture I. was published in THE LANCET of June 30th, 1900, p. 1859.

are particularly liable to leave behind them such a condition. Infective diseases may also lead to migraine by simple enfeebling of the general health without there being any evidence that the alimentary canal is specially affected, and where scarlet fever has been the forerunner of recurrent paroxysmal headaches one should be careful to exclude nephritis, which is often overlooked and may first show its presence by these attacks.

A not uncommon cause of migraine and the related headaches is the respiration of air which is contaminated by repeated breathing, and in cases where careful inquiry fails to elicit alimentary disorders or the history of an infective disease, insufficient ventilation should be thoroughly looked for. That the effect is produced rather by the poisonous material contained in the air than by deficient oxygenation of the blood is shown by the comparative rareness of migraine or paroxysmal headache in those who suffer from cyanosis, the result of chronic cardiac or pulmonary disease. It has been remarked that patients suffering from migraine usually bear evidence of being out of health; but even where the cause is a toxic one this does not hold true universally, and although in the majority of these cases we notice the languor of expression, the coated tongue, and the vascular stigmata, yet the child may look perfectly well. In such cases there is often excessive indicanuria which will guide one to the cause of the trouble. Another feature of these toxæmic patients is that their headaches generally begin in the morning, either before rising or soon after, and the reason of this is the comparative inactivity of the kidneys during sleep and the consequent accumulation of toxic materials in the blood during the night. Where fatigue or overwork bring on the paroxysms, they occur, on the other hand, most frequently during the latter part of the day. Thus the time of occurence of the seizures may help us to some degree in recognising the cause of attacks.

I have only a word to say on the subject of heredity, and that refers to cases in which there is evidence of a gouty inheritance. This means that the tissues are inclined to irregular metabolism even when they are supplied with food which is suitable to children who are free from this tendency. In such cases, therefore, successful preventative treatment will lie in regulation of the diet till it suits the individual.

Epilepsy.—Of the neuroses under consideration epilepsy is the most serious, owing to its great frequency and the difficulty of treating it when the disease has lasted any considerable time, and also in consequence of the dangers which the attacks bring with them. The remarks which I have to make shall not apply to those epilepsies which are produced by gross cerebral disease, nor to those single epileptoid attacks which not infrequently in young children mark the onset of an acute infection.

The main causes of epilepsy may be grouped as follows:—1. Heredity, direct or indirect. 2. Damage to the peripheral nerves, cranial or spinal. 3. Emotion, fright, and shock. 4. Masturbation and retained smegma preputii. 5. Commencing or disturbed menstruation. 6. Congenital syphilis. 7. Uræmia. 8. Alcohol poisoning or lead poisoning. 9. Acute infective diseases. 10. Rickets and teething. 11. Indigestion and gastro-intestinal disorders, including parasitic worms and constipation. It is unnecessary for me to go into detail on each of these points, and I will confine my remarks to the commoner or more important causes.

Emotion.—In children under the age of four years excitement, shock, and fright must be very rare as exciting causes of epilepsy, but in older children this cause is much more frequently operative. It is always necessary, however, to guard against the possible error of assuming this to be the sole cause, for in a number of instances of the disease we shall find that though fright occasioned the first fit, yet one of the predisposing factors such as, e.g., indigestion, was at work long before the fright occurred.

Masturbation.—Masturbation and other irritation of the external genitals is by most authors given as a cause of epilepsy, and I have myself met with a good many instances in which this appeared to be the case. I think, however, that masturbation is a rare cause in boys, and although I have no doubt that it may be effective in producing epilepsy in girls I have never seen a case which could be accepted as satisfactory evidence on the point. Even in boys who masturbate or who suffer from adherent prepuce with retained smegma—which sometimes smells very offensively—and who are the subjects of epilepsy, there have generally been, in my experience, other factors which could not be neglected in the endeavour to get at the true cause of the attacks. In order to illustrate this I will mention a case—that of a boy aged 12 years, of pleasant, frank, intelligent manner, but with a sallow complexion and rather thin and suffering from constipation, who had had several epileptic attacks, two of which were clearly associated with a quantity of indigestible food, and one of which was provoked by want of food beyond the usual interval, coupled with excitement and subsequent overeating. He was subject to irregularity in his meals and to injudicious feeding. He also had a prepuce which was permanently drawn forward and which concealed a good deal of retained smegma; but there was no offensive smell. It was denied that he masturbated, but the father's attention was drawn to the necessity of being on the watch for the vice. Stricter diet and general hygiene and moderate purgation were prescribed. Some weeks later the patient had another seizure and by this time the father had found out that the boy masturbated and that he was troubled with precocious sexual feelings of which he had quite willingly told his father on straightforward questioning. He was circumcised and for many months after that he had been free from seizures. Now, I shall presently have to point out the great importance which in my opinion attaches to digestive disturbances, more particularly as a predisposing cause for epilepsy, and I feel disinclined to overlook the very evident disorder of the alimentary tract which here existed. There was the constipation and the habitual irregularity of the diet both as regards time and quality of the food. On the other hand, there was masturbation, which was probably excited, like the precocious feelings, by the constant irritation to which the glans penis was subjected by the retained secretion. In the light of my present experience I would interpret the case in the following way. A predisposition of the cerebral centres was set up by the prolonged disorder of digestion, and in this state the brain was easily incited to an epileptic discharge by the stimulus of masturbation or at other times by the stimulus of an extra indigestible meal. One other case has been brought to my notice which is very parallel to that just cited. In this latter patient the considerable size of the external genitals contrasted strongly with the generally poor state of bodily development, whilst, as in the first case, the mind was active and bright. It is also worth considering whether in these two boys the immediate cause of the fits may not have been the mental excitement which the masturbation produced. I know of cases—very rare ones, certainly, but still they occur—in which the act of copulation produces in women a state of frenzy or a condition in which they act precisely as do sufferers from masked epilepsy (epilepsia larvata)—i.e., they carry out complicated acts without any evident purpose and without being in the least conscious of them at the time or afterwards. I do not know whether these occurrences happen only in women who are otherwise epileptic or not, but it is this point which has suggested to me the question as regards the excitant of the seizures in the boys just mentioned.

Menstruation.—The incidence of menstruation and the disturbances of this function in young girls are frequently blamed as exciting causes of epilepsy—and probably with justice, for it is undeniable that in many women the commencement of the fits dates from the establishment of the menstrual function. Here, again, it is not quite clear whether the effect is produced in a reflex manner or by the working of the new function upon the emotions. Possibly these two mechanisms act together. My own experience among the women at the infirmary suffering from long-continued epilepsy has shown me, rather contrary to my expectation but in agreement with the experience of others, that the fits are comparatively rarely aggravated at the menstrual periods, and in fact in the majority of these sufferers menstruation had no apparent influence either on the number or the severity of the seizures.

Rickets and teething.—These two causes are taken together because they so frequently co-exist and because in cases where they are jointly present it is difficult to gauge the true importance of each. They may, however, also exist separately. Teething may lead to epileptic fits by means of local irritation and reflex reaction. This will, of course, only occur in those children whose nervous centres are already susceptible to the epileptic discharges either through inherited weakness or through disease, and one of the diseases which is most frequently met with in this connexion is rickets. Now, we know rickets to be a disorder of metabolism and nutrition, and the central nerve-tissues must share in this disorder, with the consequence that

disturbance of their function is brought about; but it is easy to trace rickets a step further back, and we may say with confidence that the cause of rickets lies primarily in faulty diet or in faulty digestion. Rickets, therefore, comes under the more comprehensive heading of diseases of digestion, of which great class of epileptic factors we may say that rickets is a well-defined constituent.

Digestive disturbances.—Tænia, round-worms, and thread-worms may be associated with epilepsy, and I have met with each of these three causes. As before remarked, these worms never inhabit the intestine for long without producing some change in the mucosa of the gut. Very possibly in many cases a diseased state of the intestinal mucosa precedes, and renders possible, the lodgment of the worms. The intestinal change which we generally find is a chronic catarrh, in which thick masses of greyish-white mucus, stiff and difficult to remove, lie on the surface of the mucous membrane, often hiding the worms from view. By degrees, in long-continued cases, the inflammation ends in the formation of cicatrical tissue and thickening of the walls of the gut. The inflamed and altered intestine must be changed both as regards the condition of its secretion and as regards its powers of absorption. It is apparent, therefore, that besides the local presence of the worms there is an organic change in the intestine which may, if extensive, affect the absorption of food-stuffs, and which, even if of no great extent, may lead to interference with the regular course of digestion and to the formation of irregular by-products. These if absorbed will certainly not have the same effect on tissues as healthy food, but will act on them in a toxic manner. In view of the conditions just described one will certainly hesitate to explain the epileptic fits produced by intestinal worms as due to mere reflex irritation.

There are one or two further points of interest in connexion with this subject. It is said, for instance, that threadworms are comparatively rarely found to be the cause of epilepsy. This may be because they escape observation. Not very long ago there was under my care a little girl, aged eight years, who had minor seizures in a strong degree. Inspection of the stools revealed no worms for a week, although the bowels were quite freely moved every day. At the end of a week, however, a good number of threadworms were discovered in the dejecta and the association of the parasites with the seizures was thus established. The worms are therefore apt under some circumstances to escape the notice of even a trained nurse, and much more of an unobservant mother, for a considerable period; or they may be voided per anum, not continuously "with every stool," but at intervals which extend to several days. These are points worth considering when one bears in mind the somewhat severe changes which worms are apt to produce in the intestine and the great frequency with which they are associated with epilepsy. Again, epilepsy produced by worms may be unilateral in distribution, the convulsions not only commencing on one side of the body but remaining limited to that side throughout the whole course of the seizure. The same point may be observed in certain cases of epilepsy produced by overloading of the intestines, of which I shall presently give an instance. The fact is generally recognised that epilepsy caused by intestinal worms is difficult to cure even when the parasites are completely removed by proper anthelmintic treatment. There is, of course, the fallacy which has just been illustrated of the continued presence of threadworms without their being passed or recognised in the fæces, and one may be easily misled into the idea that the parasites have been successfully removed. But even when the intruders have been really got rid of the seizures are apt to continue from a persistence of a morbid condition of the intestinal mucosa which is associated with their presence. There is another reason for the continuation of the seizures—namely, the morbid habit of the nerve-centres, which once acquired is only to be overcome by prolonged treatment, but this point applies to all epilepsies whatever may be their immediate and remote causes.

There are, however, disorders of the gastro-intestinal tract, particularly of the intestine as distinguished from the stomach, other than those set up by worms, which are very frequently both the predisposing and the direct causes of epilepsy. Both in children and in adults instances of the disease meet us for which we fail to find a satisfactory explanation as to either the predisposing factor or the exciting cause. In adult males, in whom these causes are far from infrequent, there is strong evidence to show that chronic alcoholism, even when unaccompanied by kidney disease, is the predisposing factor, whilst the discharge may be produced by an extra dose of the alcoholic poison. In other cases where drink can be excluded I think strongly that the reason for the epilepsy must be sought for, and would be found, in the digestive tract. Unsuitable ingesta which act as poison, like alcohol, may be the provokers, and it is by no means necessary that they should in every instance be such well-recognised toxic agents as alcohol is. In young adolescents and particularly in children it would appear that an excessive meat diet is quite capable of putting the nervous system into what may be called the state of epileptic tension. In other patients there is catarrh of the intestine which, when it fails to attract by any marked signs the attention of the sufferer himself or of the mother, is not complained of and requires skilful questioning to be revealed. Beyond such patients whose appearance does not help us in forming a conclusion as to the cause of the epilepsy there are, however, those of another class who bear marks of their gastro-intestinal disorder which, though plain enough when attention is directed to them, are nevertheless not infrequently overlooked. I have spoken before when dealing with chorea of the frequency of certain facial signs, such as a dull, muddy complexion and furred tongue, as indicating an habitual toxæmia arising from the bowels. It is quite remarkable how often we are confronted with this complex of signs in patients whose complaint is about their epileptic fits; indeed, this state of affairs is so frequent that I have often wondered that no greater stress is laid upon the conjunction. The appearances in question may be briefly described here, since they were only touched upon under the heading of chorea. In pronounced instances the complexion is muddy, the eyes and expression are dull, and dark rings may be found round the orbits. There is a tendency to erythematous, patchy flushing of the skin of the face, neck, and chest. The small vessels on the cheeks are dilated and form vascular stigmata, such as are seen in chronic alcoholic patients and others in whom the degeneration of the blood-vessels is commencing. Often there is a tendency to acne and comedones, when the skin is often greasy-looking and secretes an excess of sebaceous material, especially about the nose. The tongue is usually coated or furred in a greater or smaller degree and the patient suffers from a bad taste, particularly in the morning. The breath frequently has a disagreeable acrid odour which at times may be very offensive—a condition which is in no way connected with any local process in the mouth. Such sufferers are often big and stout and frequently present a coarse appearance, due largely to the acne and seborrhœa. In many of them the appetite is great and even voracious. They are usually constipated, though the history of constipation is often difficult to elicit from them, for it seems as though a moderate degree of constipation becomes so much a part of a patient's life that it no longer presents itself as anything abnormal. The bowels are frequently asserted to be "quite regular" when, as a fact, they are moved every second or third day only; and it is necessary for the physician to assure himself of the physical state of the dejecta before he is justified in accepting the statement of the patient or that of the patient's mother, that there is nothing the matter with the bowels. Particularly I would lay stress on the misleading fact of the bowels being opened twice or three times a day. This generally means not that the stools are loose or copious, but that each evacuation is small, hard, and scanty, so that at each motion only a small portion of the fæcal matter lying in the sigmoid and rectum is removed, and that the true state consequently is one of constipation. On the other hand, it must not be forgotten that true diarrhœa may exist with such a disorder of the intestine and with those facial signs that I have just described. Diarrhœa, however, in my experience is very rare as compared with constipation.

In all probability the constipated condition predisposes to epilepsy by leading to a toxæmia, and not by reflex irritation. For in the first place we have the facial signs and the condition of the tongue pointing to toxæmia, and in the second place it strikes me that one very rarely encounters epilepsy when there is a mere overloading of the stomach, a condition which nevertheless has a strong tendency to set up reflex action. I am not aware of any case in which an overcharged stomach, while the food is still in that viscus, has given rise to an epileptic seizure; and in those cases in which an indigestible meal is blamed, and justly blamed, for the attack the latter does not usually

occur until at least 12 hours after the meal in question, and we know that in children in such cases an enema will often remove pieces of undigested food from the rectum. Now, from the stomach comparatively little, if any, absorption takes place, and the facts just mentioned appear to bear out the suggestion that it is only when the absorption of products of such an indigestible meal is commenced that the fits occur. This of course applies to the exciting cause of the seizure; the predisposing cause is, however, much more important and is *a fortiori* more probably a toxæmia than a state of reflex irritation.

The foundation of digestive disturbances which ultimately become complicated with epilepsy is very commonly laid at school. Thus I have seen many cases of epilepsy in young women who gave a distinct history of severe indigestion commencing while they were at boarding-schools and who never entirely recovered from their indigestion. These patients all showed in addition to their dyspeptic symptoms some evidences of auto-intoxication and with hardly an exception admitted suffering from constipation.

It is to me a remarkable fact that epilepsy is but rarely combined with anæmia. Thus out of 32 cases of women and children in whom epilepsy was connected with marked signs of digestive disorders one only showed anæmia to a degree which was recognisable by the pallor of the conjunctiva and I have not seen a single instance of epilepsy associated with typical chlorosis. When we remember how constantly chlorosis and other anæmias are combined with, and probably are due to, irregular digestion and constipation this exemption of chlorotics is certainly notable and is in want of a plausible explanation. It may of course be that the particular toxic substances which lead to anæmia are without influence on the nervous system and that, *vice versâ*, those that have a profound effect upon the latter leave the blood-forming tissues unaffected, and until we are enabled to isolate or to discriminate by their toxic effects between the several deleterious bodies which are in different circumstances produced in the alimentary canal, this is the only explanation which I can suggest.

There is nothing special in the form which the epileptic attacks assume when they are due to gastro-intestinal intoxication. Major and minor attacks occur with equal frequency and epilepsia larvata is not uncommon; it may even occur that the convulsions so produced are confined to one side of the body after the type of Jacksonian epilepsy. Thus I have seen an infant who on two successive occasions was brought to hospital suffering from marked unilateral convulsions limited to one side. On each occasion grossly unsuitable food proved to be the cause of the seizures and undigested masses were removed by enema from the rectum. Watching this child in its convulsions one would certainly have said that they were due to coarse brain disease, and although I have never seen another case so clear in character, this one seems worth noting, since instances of this kind are probably not altogether exceptional and are apt to mislead one as to the cause of the fit. The time at which the seizures take place is not characteristic in gastro-intestinal epilepsies, for the fits appear with about equal frequency in the day and in the night, and in several cases I have noted that they take place in the early morning, either while the patient is still in bed or during the process of dressing. It is noteworthy that in a considerable proportion of the gastro-intestinal cases no evidence of any hereditary tendency can be obtained.

I trust that I have made it clear that a great proportion of the epilepsies met with in everyday practice are the result of chronic toxæmia arising from the alimentary tract, and that this same auto-intoxication is the true factor in several other conditions which are universally recognised as predisposing causes of epilepsy—as, e.g., intestinal worms and rickets. It is necessary to emphasise the predisposing as contrasted with the exciting cause to which the first or any subsequent fit is attributed. It is not possible to classify the causes of epilepsy into two distinct groups—pre-disposing and exciting—without straining the facts, but in any individual case of the disease we can discern these two factors and the predisposing cause remains the same, whereas the immediate excitants of the fits may vary, and will be, now fatigue, then excitement, or again injury or pain.

Pathology.—The diseases under consideration have, then, the following etiological points in common. They are produced by a group of emotional causes and, on the other hand, by a group of toxic causes, together with each of which hereditary predisposition has an important influence. The toxæmic element is more effective than the emotional in all these maladies excepting saltatory spasm. The further remarks which I have to make on the pathology of these disorders shall be limited to the subject of self-intoxication from the alimentary canal, which has been shown to be a factor of first importance.

We may conveniently divide the gastro-intestinal disorders which lead to toxæmia as follows:—

1. *Excessive amount of food.*—Over-eating has a great effect in setting up disorder of the alimentary canal. The habit is a common one among the children of the lower classes, but it is by no means confined to them. We may explain its action as follows. Normally the glands which produce the digestive juices secrete them in quantities which are capable of dealing with a certain volume of food. Habitual excess of food or too frequent meals will no doubt stimulate the glands to yield a proportionate increase of their secretion for the time being, but such an over-strain, if long continued, is apt to end in glandular inadequacy and consequent incomplete digestion. The incomplete digestive products may be absorbed; or in the absence of a sufficient amount of the digestive fluids bacterial decomposition of the intestinal contents takes place, and the products of the same are taken up by the blood-vessels and lacteals.

2. *Unsuitable food.*—Food unsuitable either to the age of the patient or to his individual digestive capacity is likewise often the cause of those gastro-intestinal conditions which are found associated with the neuroses, and very frequently such dietary errors signalise themselves by producing the facial appearances which have been described. Reference has already been made to the fact that an excess of meat food—and probably the same would hold good of excess of any other proteid material—is apt to be associated both with dreaming, enuresis nocturna, and epilepsy, and I think that when a fault is discovered in the nature of the food it is the proteid constituents which are usually to blame.

3. *A catarrhal condition of the stomach or of the small intestine.*—This may arise from various causes, as, for example, dietary errors, intestinal worms, or infective diseases. This condition may be accompanied by diarrhœa, or, more commonly, by constipation. In speaking of the local effect of intestinal worms I have already detailed the manner in which such catarrhs act and how they may long outlast their original cause.

4. *Constipation.*—Constipation, arising from catarrh of the intestine or faulty diet or from mere habit and encouraged by neglect is undoubtedly one of the most common predisposing causes of all the neuroses here considered, and its effect is produced partly by the delayed elimination of fæcal matter which therefore has a chance of being re-absorbed by the intestine and partly by the encouragement which it is shown that bacterial growth within the intestine receives when the fæces are retained. In the absence of a verbal admission by the patient of any of these digestive disorders we may observe the signs which have been fully described and the significance of which as an index of auto-intoxication has been pointed out, or we may find indicanuria. Indican is derived from indol, which latter is formed in the intestine by the bacterial decomposition of albuminous substances. A very little indican is commonly present even in the urines of healthy persons, but a considerable excess of the same, such as I show you in these specimens, is always accompanied by disturbed general health. We may, therefore, say that excess of indican in the urine is always associated with toxæmia, and this toxæmia arises (with rare exceptions, in which the source is decomposing pus) from the intestinal canal. Indol itself may possibly be toxic, in view of its origin through bacterial action and of the fact that it is unlikely to be a nutrient substance, for all the familiar organic food stuffs contain oxygen, and indol is deficient in this element. Indol is formed from the nitrogenous food stuffs and is so far the only decomposition product of intestinal origin which we have the means of detecting in the urine. But it is quite probable that analogous products are formed from both carbohydrate and fatty articles of diet under the influence of constipation or of intestinal catarrh. If this be so we ought to meet with bodies of the constitution of the alcohols and of the fatty acids, but I am not aware that any such have been certainty detected in the urine, and it is possible that they undergo such changes before they are finally excreted with that fluid as to be no longer recognisable, or that they are completely oxidised in the blood and excreted from the lungs.

Excepting the sign of indicanuria we have no chemical test which proves that auto-intoxication from the alimentary canal is in progress. There is, to be sure, the fact, first described in detail by Bouchard, of the toxic action of the urine, and we might expect to find in the case of self-intoxications special results following the injection of such a patient's urine into the blood of an animal. But so far as I am aware the poisonous effects of the urine of healthy persons have hitherto proved to be identical in nature with those obtained with urine from patients suffering from blood-poisoning, though less in degree, and the only exception to this rule appears to occur when the urines of certain infective diseases—e.g., pneumonia—are employed. This physiological test would, however, not be applicable to the bedside, even if it should in the end prove useful in detecting special poisons in special gastro-intestinal disorders. A point to which I have previously drawn attention is the prominence of the toxæmic symptoms of malaria, languor, and sometimes vertigo, in the early morning, and in this connexion it is highly interesting to note one result of Bouchard's experiments—viz., that the urine secreted during the night is, though more concentrated, materially less toxic than that eliminated during the hours of mental and bodily activity.

TREATMENT.

In view of so many common points in the production of these neuroses their treatment must possess certain common features which shall first be dealt with.

From the stress which has been laid upon disorders of digestion and faulty diet as a cause of nearly all these diseases it follows that correction of dietary errors is one of the main points requiring attention. In the majority of cases in which the feeding is at fault it is advisable to cut down the amount of meat which the child consumes. Meat once a day will nearly always be sufficient, and that once should be at dinner-time in the middle of the day while there are still some hours of muscular activity before the child. It is seldom necessary or advisable to remove meat altogether from the dietary, for it is nearly always an excessive quantity of meat which leads to the trouble, not meat in a small or moderate amount. So long as the meat is good there is, I believe, not much difference between beef, mutton, rabbit, fowl, game, &c., but fish may with advantage be substituted for butcher's meat. Light puddings and green vegetables may be given and potatoes in moderation. In fact, it is not so much a question of prohibiting any article of diet as of regulating the amount. In many children the entire bulk of food requires reducing. In severe cases of enuresis it is sometimes (as in the case which I have quoted) advisable to stop meat altogether for a period and then to allow it again in a very small quantity. Sufficient mastication and moderate rest after meals should be insisted on, as they greatly help digestion, and the child should not leave the house after breakfast until the bowels have been opened.

It is plain, also, that in most cases the action of the bowels demands attention, since the prevention of an auto-intoxication from the intestine depends firstly on regular and sufficient defæcation. As cathartics the saline purgatives are invaluable, at all events to begin the treatment with, and since it is advisable not to give drugs more often than necessary they are best administered in the shape of a single dose of mixed sulphates of soda and magnesia one hour before breakfast, or in a smaller dose last thing at night. Any of the natural aperient waters may be substituted for this mixture. Calomel (or calomel combined with a small quantity of colocynth and rhubarb) is also extremely valuable in this class of cases. Senna, aloes, and other drugs which act mainly on the lower intestine, are less indicated, for it appears that the groups of aperients first named act largely by stimulating the flow of bile and by thus helping the liver to eliminate whatever toxic materials it has removed from the portal blood stream. Whichever drug be given the object to be attained is one large stool, of porridge-like constituency, to be passed preferably before or shortly after breakfast. Again, we want to convert habitual irregularity of the bowels into habitual regularity, and to this end it is necessary to give, not an occasional purge when the bowels have been obstinate for a day or two, but a regular course of this daily treatment, extending over three or four weeks, to be followed by a gradual diminution of the dose, administered first on alternate days, then at longer intervals. This combined with the dietary measures prescribed will usually be followed by complete success in children, and any excess of indican, if present at the onset, usually disappears under these therapeutic measures, but sometimes it continues to be present in considerable quantity, showing that in spite of the purgation an excess of microbial products is absorbed. In such cases the so-called intestinal antiseptics naturally suggest themselves, the chief of which are sulpho-carbolate of soda, salol, phenol, mercurial salts, charcoal, and possibly arsenic. All these, excepting phenol and arsenic, I have tried, and though each has proved useful I cannot say that any one of them can be relied upon to remove the trouble entirely and in all cases. Those which have in my hands proved the most successful are sulpho-carbolate of soda and charcoal. The first is, however, very apt to give rise to headache and must therefore be carefully watched, and on the whole I give the preference to vegetable charcoal given in 30 grain doses twice daily. Perchloride of mercury, the most powerful of antiseptics, has not in my experience had the desired effect—at least, in such doses as I have cared to give to children. Arsenic in comparatively large doses I have not yet tested in this connexion.

Tonics may be of use in certain of these neurotic conditions where there is enfeebled general health due to previous disease, but their utility is far less than that of the remedies which act upon the intestines. They do, however, improve the appetite and probably hasten the general metabolism, and they may therefore be usefully combined with the intestinal drugs. Their employment alone, however, is to be deprecated where there is any active auto-intoxication, for in such cases they do not strike at the root of the trouble and only delay improvement by deferring the employment of the proper remedies.

In conjunction with the measures which I have mentioned above to be applied in all those cases in which self-intoxication is the main cause each one of the neuroses requires some special treatment.

Chorea.—Besides seclusion, darkness, and quiet, undoubtedly the most effective treatment is that by arsenic in doses of about 15 minims of Fowler's solution twice or three times daily, as advised by Dr. Murray. The success of this method is quite another thing than that attained with arsenic in small doses, and is much more quickly gained. Some evidences of poisoning are apt to arise under this medication, notably nausea and vomiting, and when these occur the best thing is to diminish the dose, not to stop the drug.

Enuresis nocturna.—This may be successfully treated, as a rule, by giving bromide of potassium, with either tincture of belladonna or of hyoscyamus, as a nightly dose. It is, moreover, well to administer some alkali, such as citrate of potash, in order to diminish the acidity of the urine, which excessive acid reaction is itself of irritating effect. Of course, should bacteriuria be present it is necessary to locate the cause of the same and to deal with it.

Migraine.—Attacks of migraine which depend upon auto-intoxication may, I believe, be successfully cut short by the administration of a smart emetic, and I have known several adults who have asserted that this course more certainly relieved the attack than any other. Of course, antipyrin sometimes succeeds in these cases, but by no means always. It is not clear how emetics produce their effect, but it may be that some of the toxic material is excreted from the blood by the gastric mucous membrane and re-absorbed, in which case an emetic will remove it. On the other hand, it is possible that the act of vomiting stops the headache by the violent stimulus which it affords to the nervous system. I do not think that emetics are ever useful in those migrainous attacks which result from prolonged overwork of the body or mind.

Tetany.—For the spasm of tetany the bromides, so far as my experience goes, are by far the most efficient remedies when employed together with the proper treatment for the catarrh of the respiratory or intestinal tracts. Galvanisation is recommended, but I have never had occasion to employ this measure, and I cannot help thinking that in most cases it is unnecessary. Quiet and darkness are strong aids to the successful treatment of this affection.

Dreaming and nightmare.—For these symptoms no treatment is required beyond that which deals with the primary cause.

Epilepsy.—Undoubtedly the best drugs to employ in epilepsy are the bromides. I am accustomed to give equal quantities of the potassium and ammonium bromide, the total dose to be determined by the result upon the seizures. This combination tends, I think, to resist the depression

which is apt to ensue when the potassium bromide alone is used for long, and for long these drugs must be administered if any permanent good is to be done. They probably act directly upon the cerebral centres. As I had occasion to point out before, epileptic seizures are very apt to continue even when the predisposing cause has apparently been removed, and their continuance is no doubt due to the fact that a morbid habit of action is acquired by the nerve-structures concerned in the convulsive discharge, a habit which is favoured by every seizure. Taken in hand early and treated with perseverance epilepsy is by no means so hopeless a malady in children as one might be led to believe by seeing it in the adult chronic epileptic. Should intestinal worms appear as the cause of this disease, and the proper anthelmintic remedies be administered with apparent success, one must nevertheless bear in mind the obstinacy of these parasites and the fact that they are generally present in numbers. A child can certainly not be regarded as being free from the intruders until the stool has been repeatedly found clear of the ova, and in the case of tapeworms the head must be found. For oxyuris vermicularis I am in the habit of prescribing infusion of quassia internally, coupled with mild purgatives. For tænia male fern is the most successful drug, provided that it be given when the intestines are empty through fasting and that it be helped by a cathartic remedy; but whichever parasite it may be the altered condition of the intestinal mucous membrane will have to be remembered, and this condition will require careful dieting, and possibly saline purgatives, to be continued over a considerable period of time.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the summer session, 1900:—Barker Anatomical Prize, £21: J. F. Peart. Carmichael Scholarship, £15: A. Charles. Gold and Silver Medals in Operative Surgery: gold medal, E. A. W. Henley; and silver medals, F. W. Lamb and A. H. B. Hartford. Practical Histology: R. W. Burkitt, first prize (£3) and medal; and R. G. Allen, second prize (£1) and certificate. Practical Chemistry: Miss J. Bell and A. N. Crawford (equal), first prize (£2) and medals. Public Health and Forensic Medicine: J. F. L. Keegan, first prize (£3) and medal; and Miss H. A. Hall and W. R. Meredith (equal), second prizes (£1) and certificates. Materia Medica: A. T. Mulhall, first prize (£3) and medal; and J. R. MacManus, second prize (£1) and certificate. Practical Pharmacy: J. J. Connolly, first prize (£3) and medal; and Miss L. Smith, second prize (£1) and certificate. Biology: B. H. Peters, first prize (£3) and medal; and J. J. Connolly, second prize (£1) and certificate. The preliminary examination for the next session will be held on Sept. 26th and 27th. Regulations and students' guide are now ready.

THE BRISTOL ROYAL INFIRMARY.—The accommodation for nurses at the Bristol Royal Infirmary having been found inadequate the home which was fitted up for some of the nurses in 1886 and enlarged in 1896 has been again considerably enlarged and improved. The entire structure now contains bedroom accommodation for 93 nurses. There are also recreation-rooms, reading-rooms, bath-rooms, &c. The whole of the building is lighted by electricity. By the acquisition of an adjoining piece of ground a garden has been made which is sufficiently large to provide a tennis court and other means of outdoor recreation. The cost of the new building, including an extension of site and furnishing, has been about £8600. The expense of furnishing has been defrayed by the carnival which was held at the Zoological Gardens, Clifton, in 1899, and the committee hope that the residents of Bristol, recognising the need of reasonable comfort for the nurses, will subscribe the requisite funds.

THE NOTIFICATION OF MEASLES.—At the meeting of the Ottery St. Mary District Council held on July 6th one of the members proposed that measles should be made a notifiable disease, but after discussion it was determined to postpone further consideration of the matter for three months and in the meantime to obtain the opinion of the Local Government Board upon the subject.—At the meeting of the New Quay (Cornwall) District Council held on July 7th it was decided to continue the inclusion of measles as a notifiable disease, but that in future the notification should be 1*s.* instead of 2*s.* 6*d.*, the medical men of New Quay having agreed to such a reduction.

The Croonian Lectures

ON

THE DEGENERATION OF THE NEURONE.

Delivered before the Royal College of Physicians of London on June 19th, 21st, 26th, and 28th, 1900,

BY FREDERICK W. MOTT, M.D. LOND., F.R.S.,

PATHOLOGIST TO THE LONDON COUNTY ASYLUMS; PHYSICIAN-IN-CHARGE OF OUT-PATIENTS, CHARING-CROSS HOSPITAL.

LECTURE IV.[1]

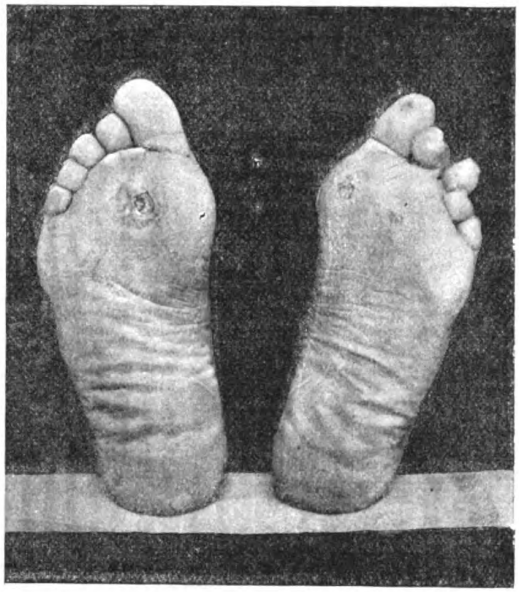
Delivered on June 28th, 1900.

SOME CHRONIC TOXIC CONDITIONS.

MR. PRESIDENT AND GENTLEMEN,—So far I have dealt with experiences relating to poisons producing acute or subacute changes in the nerve-cells. I shall now refer to the effects of chronic poisoning of the system, especially in reference to two factors which are the most potent, the most prevalent, and the most persistent poisons in the production of the degeneration of the neurone and which frequently act in combination, affecting not only the nervous system of the individual but also of the offspring. Such are alcohol and syphilis.

THE CLOSE RELATIONSHIP IN THE ETIOLOGY AND PATHOLOGY OF TABES AND GENERAL PARALYSIS.

Syphilis is the best example of a poison probably, though not proved to be, of microbial origin which has a selective influence upon the nervous system with a remote effect; it is the most important factor in the production of two progressive degenerations of the nervous system, one affecting especially the exogenous afferent spinal neurones—namely, locomotor ataxy; the other affecting the association systems of neurones of the cerebral hemispheres, especially of the frontal and central convolutions—namely, general paralysis of the insane. A striking instance of the selective action of the syphilitic poison is shown in the fact, first pointed out by Sir William Gowers, that only in persons affected with acquired or inherited syphilis is the symptom known as the Argyll-Robertson pupil found; indeed, it is sometimes the only symptom. Seeing that this is the most common objective phenomenon in the two diseases mentioned it strengthens the presumption, based on experience, that the syphilitic poison is the cause of the disease in the majority of instances. It is the opinion of many authorities—and I must say that my experience supports it—that locomotor ataxy and general paralysis are one and the same morbid process, affecting different parts of the nervous system. They are, in my opinion, both a primary and progressive decay of the nervous elements and are etiologically, clinically, and pathologically very closely related. At a discussion held at the Pathological Society of London I supported the view that tabes and general paralysis are one and the same disease affecting different parts of the nervous system. It was asked if this be so, how do you explain the fact that in general paralysis it is the brain, and especially one particular part, which is affected, while in locomotor ataxy it is the cord? Let us consider the effects of poisons like alcohol, lead, ergot, lathyrus, and diseased maize (pellagra). They may produce both peripheral nerve and cord changes together with brain changes in the same individual. It is the individual, his occupation, and habits which determine the seat of the morbid process. In some cases, however, the cord symptoms, on the one hand, predominate and the brain symptoms may be slight, or even absent; on the other hand—and these are the cases of lead and alcoholic poisoning which come into the asylums and are not seen in the hospitals—we have the brain symptoms predominant and the paralytic symptoms often less defined, overshadowed by the brain affection or even absent. So it is with general paralysis. Cases come into the hospitals with Argyll-Robertson pupils, marked paresis, and speech affection, but with the mental symptoms only comparatively slightly developed. Likewise



[1] Lectures I., II., and III. were published in THE LANCET of June 23rd and 30th, and July 7th, 1900, respectively.

numerous cases of tabes attend the hospitals for a considerable time and then marked mental symptoms develop, when the case is certified as tabetic general paralysis. In all these degenerative diseases we have more than one factor in operation, and I quite agree with Edinger in his opinion that *stress* will determine the initial localisation of the degenerative process. I do not know that we can learn very much about these primary degenerations from experiments upon animals. However, much valuable knowledge undoubtedly has been obtained by the effects of poisons in producing acute or subacute degeneration of the neurones. Certainly animals have not been inoculated with syphilis. Tuczek, who first described the changes in the nervous system in ergotism and pellagra, was unable to produce these degenerative processes in animals by long-continued feeding with diseased rye, nor have other experimenters been successful with injection of ergotin and sclerotic acid. Likewise, alcohol and lead administered to animals do not produce the characteristic clinical and pathological conditions found in man. Moreover, many other poisons, the products of micro-organisms, produce different effects in man to those produced in animals. The close association of tabes and general paralysis is to my mind clearly shown by the fact that there are a considerable number of cases in which it is difficult to say whether they should be classed from their clinical symptoms and morbid changes found post mortem as tabes with mental symptoms or as cases of tabetic general paralysis. I have seen cases in which the diagnosis of general paralysis has been made because the patients were suffering with mental symptoms indicating that disease—viz., maniacal or melancholic symptoms and delusions associated with ataxy. After a time the mental symptoms have cleared up and the case has then been called tabes. Again, I have frequently seen cases of tabes which begin with all the characteristic phenomena of this disease and then terminate in progressive dementia and paresis, dying in an asylum from general paralysis. Symptoms which are looked upon as characteristic of tabes, such as grey atrophy of the discs, are not at all uncommon in general paralysis (10 per cent.) and I have met even with symmetrical perforating ulcers (Fig. 1) and Charcot's joint. I have recently examined 12 cases of the tabetic form of general paralysis in which the changes in the brain (naked-eye and microscopical) were characteristic of general paralysis and the cords showed the characteristic lesions of tabes. My experience would point to about 10 per cent. of the cases of general paralysis being associated with tabetic cord lesions. The etiological relationship of the two diseases is almost identical; both affections occur usually in the prime of life, are more prevalent among townspeople, affecting men of all grades of society, but as a rule only women of the lower and lower middle class. Again, juvenile general paralysis and juvenile tabes probably occur only in the subjects of congenital syphilis and the sexes are affected with equal frequency. I have met with one case of the latter and 30 cases of the former with 24 post-mortem examinations. In 80 per cent. of the cases of juvenile general paralysis a definite history or signs of syphilis were obtained. A considerable number of cases have now been recorded of married couples being affected with general paralysis. I have recently seen a man who had well-marked signs of syphilis who subsequently died from the tabetic form of general paralysis; his wife, who had healthy children by the first husband and none by this second, is now dying from general paralysis. Dr. T. Buzzard related a similar case at the discussion referred to.

SOME FACTS CONCERNING THE ETIOLOGY AND PATHOLOGY OF GENERAL PARALYSIS.

There are two types among the juvenile general paralytics: (1) in which the syphilitic poison seemed to have produced an arrest or impaired development of the higher centres, so that the child was weak-minded or imbecile; and (2) in which the child was mentally capable, in some cases highly intelligent and active-minded. The cause of the degenerative process in most of these cases seemed to be associated with the increased psychical *activity*, which must of necessity develop after puberty, when new emotions, objects, and ambitions are awakened by the sexual instinct and the struggle for existence. That psychical activity plays a very important part in this disease as affecting adults is clearly shown by the following facts: the sufferers are nearly all townspeople with a quick reaction time, ambitious and energetic, and the first symptom of the disease may be undue mental activity, approaching now and then to that of genius. It might be argued that a large number of these people are from the lowest and least educated classes; still, I am convinced that they belong to the mentally active class. Not only do we find the people affected possess mental activity but also usually sexual proclivity, and it is very difficult to decide whether the increased sexual activity so frequently met with in the early stages of this disease is a cause or an effect. But all forms of mental excitement are associated with fatigue and too often the neurasthenic condition which precedes the more definite symptoms of the organic brain affection leads to alcoholic excesses, and it is often very difficult to decide whether a case is one of *mania à potu* or of general paralysis. The two are frequently combined, and if so the disease runs a more rapid course. The researches of Bonhofer and Trömner have shown that acute degenerative changes may occur in the cortical cells as a result of acute alcoholism; and I have found, and can therefore agree with Jolly, that in cases of alcoholic dementia there exist organic changes affecting the superficial layers of the cortex and causing atrophy of the tangential fibres. It is, then, probable that although alcohol will not of itself produce general paralysis it will materially increase the rapidity of the progress of the disease. Kraft-Ebbing sums up the etiology of this disease in two words—"civilisation" and "syphilisation"; and he brings forward very strong arguments in favour of the important rôle of syphilis. The recent report for the year 1899 by Dr. J. Warnock from the Egyptian Hospital for the Insane entirely upsets this view. He states: "During 1899 57 general paralytics were under care out of a population of 500. The large towns furnished nearly all the cases of this disease, and syphilis was known to be the cause in 29 of the 35 cases admitted. 24 of them were native Egyptians."

FIG. 1.

Why should general paralysis be associated especially with atrophy of the frontal and central convolutions? It has already been pointed out that in these regions venous stasis is most likely to occur. Psychical activity is associated with hyperæmia of the brain and congestion; those portions of the brain in which the mechanical conditions favour this congestion in the most marked degree would be more likely to suffer from the effects of the congestion. The whole cerebrum and spinal cord waste in general paralysis, but certain regions are earlier and more markedly affected than others—viz., the frontal and central convolutions (*vide* Figs. 2, 3, and 4). These are the regions whose veins drain into the longitudinal sinus and in which, therefore, for reasons previously mentioned, congestive stasis is more liable to occur. If it be admitted that owing (in the majority of cases) to the influence of the syphilitic poison the durability of the nervous system has been lowered, increased psychical activity will tend to exhaustion and disturbance

FIG. 2.

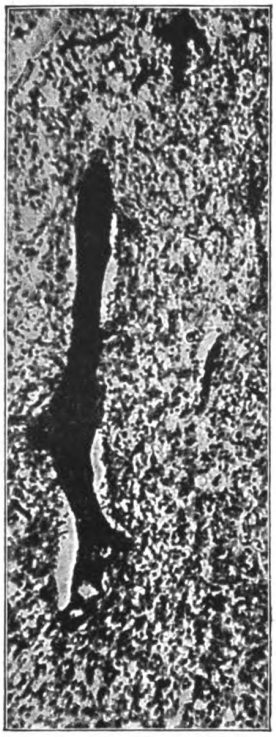


FIG. 4.

FIG. 3.

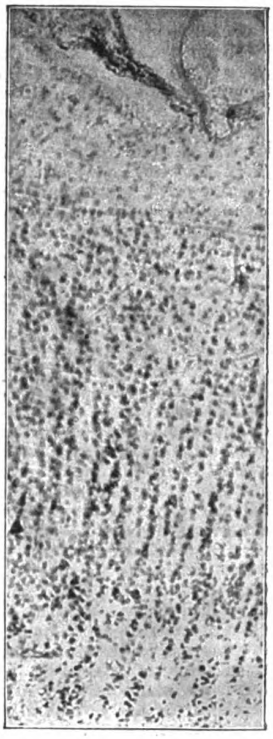

FIG. 5.

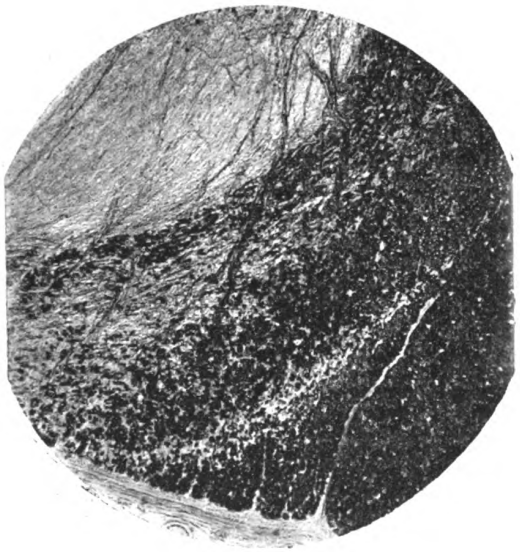

FIG. 6.

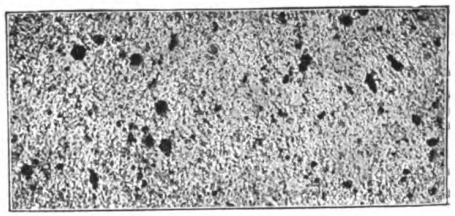

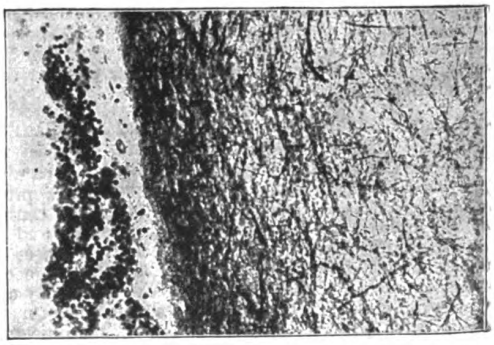

FIG. 7.

of the normal nutritional equilibrium of the neurones. But psychical activity will cause hyperæmia and congestion of the brain, and in regions where there is a tendency to stasis the congestion may persist, especially if it leads to insomnia. A vicious circle becomes established by conditions which tend, on the one hand, to perpetual venous congestion in certain regions, and, on the other hand, to increased excitability of the neurones; these factors mutually interact. It has been argued that in Mohammedan countries where syphilis is rife general paralysis is unknown.

Venous congestion (according to the researches of Waller who has shown that CO_2 increases the excitability of nerve) may lead to hyper-excitability of those regions in which the stasis occurs. Likewise there is probably an impaired supply of arterial blood to the brain for the following reasons. The experiments of François Frank show that excitation of the Rolandic area of the cortex causes contraction of the arterioles and rise of blood-pressure; observations which I have made upon the blood-pressure in general paralysis by Hill's sphygmometer entirely accord with the results obtained by Leonard Hill and Craig. There is a considerable rise in the arterial pressure above the normal and this is increased markedly during the occurrence of seizures, whether congestive or epileptiform. The blue condition of the skin and the coldness of the hands and feet of patients suffering with general paralysis suggest a small amount of blood in the arterial system and a large amount in the venous. Although we find this high arterial pressure there is seldom marked hypertrophy of the left ventricle, and I have found that if a patient has a great number of epileptiform seizures the arterial pressure falls and right heart distension and sometimes a condition of asphyxia arise, with great engorgement of the veins, and death in consequence. The heart muscle in these cases exhibits early and often extensive fatty degeneration, due to a combination of causes—insufficient oxygenation of the blood, auto-intoxication probably from fatigue products, and increased destructive metabolism owing to the much greater resistance to be overcome. Not only the heart but also the striated muscles show this change. I could not find evidence of degeneration of nerves to account for this change, neither do I believe this to be the effective cause, seeing that exactly the same changes in heart, diaphragm, and other striped muscles have been found by me in seven cases of status epilepticus.[2] Some of the latter patients prior to the fits were in perfect health. In connexion with this I may mention that the venous congestion of the brain caused by the status epilepticus produced marked changes in the cells of the cerebral cortex, changes which corresponded with the appearances presented by many of the large pyramidal cells in general paralysis and not unlike those found in experimental anæmia with convulsions. There was great swelling of the cell (œdema), disappearance or disintegration of the Nissl granules, often eccentric position of the nucleus, and dilatation of the peri-neuronal and peri-vascular lymph spaces. Moreover, epilepsy frequently ends in dementia, and we find in such cases atrophy of the tangential super-radial and inter-radial association fibres, a condition which is always found in general paralysis even in the earliest stages before any fits occur. Dr. George Watson, who has looked over a large number of my specimens, reports that in 20 cases which he has examined he found the tangential fibres, the super-radial and inter-radial fibres atrophied in all the 16 cases of general paralysis, but that of these 16 none showed any recent change by the Marchi method; consequently we must suppose the atrophy was of some considerable standing, and probably years before the patient comes to an asylum a regressive change has commenced in these latest morphologically-developed structures. Occasionally I have been able to show that the tangential fibres of Broca's convolution are more atrophied on the left than the right side when the left hemisphere has weighed less than the right. The four cases in which he did not find atrophy of the association systems mentioned were primary degenerations of projection systems—viz., two of amyotrophic lateral sclerosis, one of combined sclerosis, and one of universal syphilitic arteritis. In a considerable number of the cases of general paralysis there was recent degeneration of the radial fibres, especially in those cases where there had been epileptiform seizures. The perivascular lymphatics also contained the fatty products of degeneration. We can thus understand that a number of contributory factors may arise to establish a vicious circle which is continually enlarging until a fatal termination occurs. Such factors may not only lead to rapid destruction of the neurones or nervous elements, but by irritation lead to a proliferative formation of the neuroglia cells, and we can account for the ependymal granulations almost invariably met with in this disease by the irritation caused by an altered cerebro-spinal fluid. They are, however, not found exclusively in general paralysis.

[2] Vide Archives of Neurology, p. 493.

GENERAL PARALYSIS A PRIMARY DEGENERATION.

The morbid process in general paralysis has been considered by Mendel and many other authorities to be a primary meningo-encephalitis. I would advance the following reasons for considering it a primary degeneration of the neurone with secondary meningo-encephalitis:—1. Its relation to tabes dorsalis and the probability of its being the same morbid process due to the same cause (syphilis) commencing in a different part of the nervous system. 2. The existence of the Argyll-Robertson pupil in the majority of cases. 3. The existence of grey atrophy of the discs in a number of cases, much more frequent than can be explained by mere coincidence. The last two symptoms cannot be explained except by a primary atrophy. 4. The evidence of a wasting of the whole nervous system, but out of all proportion to the evidences of inflammation affecting some parts more than others. This wasting must be primary in the nervous system and not secondary to bodily disease, for in no cachectic disease or even in starvation do we find extensive wasting take place. 5. The thickening of the pia-arachnoid membrane is proportional to, and corresponds with, the degree and locality of the atrophy; so it is with tabes. 6. In many cases of tabes, especially those with mental symptoms, atrophy of the tangential and super-radial association fibres of the brain are found quite similar to but often in different situations to general paralysis. 7. In diseases with well-marked meningo-encephalitis, about which there can be no dispute that it is primarily an inflammatory process, we do not find this extreme atrophy. In illustration of this I would call attention to two cases of African lethargy which I had the opportunity of examining and of describing[3] for the first time the histological changes in the central nervous system. Throughout the whole central nervous system in both these cases there was evidence of a profound and widespread chronic inflammatory process. The whole of the perivascular lymphatics were choked up with mononuclear leucocytes. The pia-arachnoid membrane was similarly infiltrated, indicating the existence in the cerebro-spinal fluid or blood of an irritant poison the nature of which I was quite unable to discover, although the most painstaking efforts were made by myself and Dr. Bulloch, both post mortem and during life, to discover a micro-organism. The only abnormal condition that was found in the blood of these negroes, as also in a previous case of Dr. Stephen Mackenzie's (the tissues of which by his courtesy I was able to examine and observed similar histological changes), was the existence of the embryo filaria perstans in the blood. The evidence of this being the cause of the symptoms or of the morbid process found in the nervous system is wholly inadequate. Although there was this chronic inflammation, yet throughout the nervous system there was far less cellular atrophy and nerve-fibre destruction, even in the most advanced case, than one meets with in quite the early stages of general paralysis. In fact, the brains showed little or no atrophy or change to the naked eye; and microscopically there was very little disarrangement of Meynert's columns in one case. The weight of the brains showed little deviation from the normal in one case and none in the other, whereas the bodies were extremely emaciated in both cases. I think this evidence tends to show that there is a primary atrophy in general paralysis and that the inflammatory and vascular changes are secondary complications. Primary degeneration of the neurones may affect the afferent, efferent, or association systems, singly or combined, and in the tabetic form of general paralysis all three may be affected.

[3] Brit. Med. Jour., 1899.

PRIMARY DEGENERATION OF THE AFFERENT SYSTEM OF NEURONES.

In tabes we have an example of degeneration of the

afferent projection system which, for reasons already mentioned, is probably due to nutritional failure on the part of the posterior spinal neurone, by which parts most remote from the centre of nutrition undergo a regressive atrophy. The cells of origin seldom undergo marked changes unless pigmentation can be considered evidence of degeneration, but there seems to be some reason why the cells of the posterior spinal ganglia should be able to maintain a trophic independence. Possibly it may be the existence of the capsule, or possibly the cells receive stimuli from the viscera by sympathetic branches, or, lastly, it may be that they have become more or less independent of the influence of stimuli by the impulses from the periphery travelling directly across the T-shaped process. Again, after section of the posterior spinal roots I did not find any change in the posterior spinal ganglion cells. Moreover, we know that in amputation cases of long duration, although the nerves and posterior roots waste, the spinal ganglion cells undergo little change. It is particularly the central projection of the neurone that undergoes the degenerative process in tabes, and from the experimental evidence above adduced this would not suffice to cause changes in the cell. The peripheral portion of the neurone—viz., the sensory peripheral nerves—have been shown to undergo regressive atrophy and degeneration from the termination towards the centre. We know that the peripheral portion of the T-shaped process is ensheathed by the hollow mesoblastic cells forming the sheath of Schwann, and which we have shown for many reasons probably exercises an indirect trophic influence upon the long axis-cylinder process.

Again, in tabes, the idea that a sclerosis of the posterior columns produced by an irritative proliferation of the glia tissue is the initial morbid process causing a secondary degenerative atrophy is the result of confusion of cause and effect. The overgrowth of the glia tissue is the result of, and proportional to, the primary progressive atrophy of the nervous elements, for we cannot suppose that the glia tissue would electively destroy exogenous fibres, leaving the endogenous intact. In support of this statement I show a photomicrograph of the sixth cervical segment of the spinal cord of a monkey in which the third, fourth, fifth, sixth, and seventh cervical and first, second, and third dorsal posterior spinal roots were cut on the left side. The eighth cervical, which especially supplies the hand, was not cut. This animal was kept alive six months, and it was after a time very difficult to determine upon which side the operation had been performed, as it used each hand equally well, thus behaving entirely different to the animals which had had all the roots cut.[4] The result of this operation is shown in two bands of sclerosis in the posterior column on the side of the divided roots, with an area of normal fibres corresponding to the undivided root lying between (Fig. 5).

It will be observed in this photo-micrograph of the sixth cervical segment that fine fibres are passing across the area of sclerosis to the grey matter of the posterior horn; in not a single section of all the segments of the upper part of the cord could I find the absence of these fibres, which could only be terminal branches of the undivided eighth root. This points to the probability of the overlapping of roots of spinal segments. It certainly shows that sclerosis does not cause atrophy of fibres, for here is a band of fibres lying between two definite bands of sclerosis with delicate fibres passing across the sclerosed area. Obersteiner has maintained that the degeneration of the posterior columns is due to a meningitis affecting the roots at their entry, thereby compressing the accompanying nutrient vessels; but there are so many facts against this theory which will occur to everyone upon consideration that I need not mention them. Suffice it to say that one does not find this same degeneration of the posterior columns in obvious cases of meningitis, syphilitic in origin. Obersteiner figures specimens stained by the Pal method showing as the fibres pass through the membranes to enter the cord disappearance of the staining. This, however, must not be taken as indisputable evidence of degeneration at this particular point because the anterior roots sometimes show a similar defect in staining upon their emergence from the cord. Moreover, the meningitis theory does not explain the changes in the peripheral nerves met with in this disease, nor does it explain the affection of the posterior roots as far back as the ganglion, leaving the anterior roots quite intact. That some anatomical condition of the circulation in the posterior columns may act as a contributory factor, as occurs in the frontal and central convolutions in general paralysis, is possible, especially when one considers the effects of cerebral tumour in the production of degeneration limited to the posterior columns (Hoche, Batten).

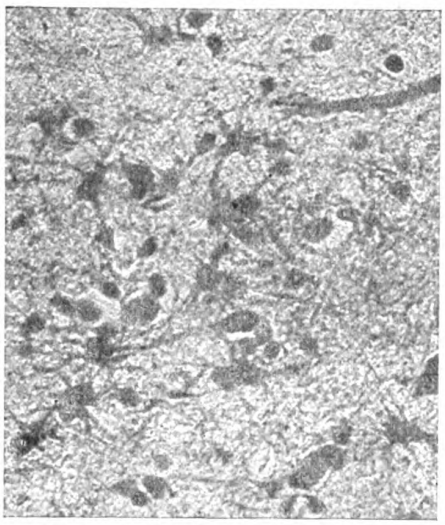
[4] Mott and Sherrington: Proceedings of the Royal Society, 1895.

PRIMARY DEGENERATION OF THE EFFERENT SYSTEM.

In amyotrophic lateral sclerosis we have an example of a systemic degeneration affecting the motor efferent system of neurones from cortex to periphery. I have had the opportunity of examining three typical cases of this disease; in all three I have found degeneration of the whole efferent system comprising the cortico-spinal neurone and the spinal muscular neurone, the degeneration being limited to these neurones alone. This was pointed out by Sir William Gowers in the first edition of his manual. Certain groups of the motor spinal neurones we know from clinical and microscopical observation are affected before others—e.g., the postero-external group in the eighth cervical and first dorsal segments of the cord is especially proved to be the seat of the earliest and most severe change in a large number of cases. This is a group of neurones which presides over the small muscles of the hand. I am of opinion that the morbid process in these systemic degenerations commences at the periphery of the neurone and extends back towards the trophic and genetic cells of origin, finally, in prolonged cases, causing the destruction of the cells themselves. The arguments I would advance in favour of this view are that in some cases of amyotrophic lateral sclerosis degeneration could only be followed as far as the pyramids, in others to the crus cerebri, while in other cases, published by Charcot and Marie, Kahler and Pick, and Kowjenikoff, the atrophy had extended to the pyramidal cells of the cortex. In the case referred to by the last observer there was even atrophy of the motor convolutions with thickening of the membranes; this I have also observed in one of the three cases I have above mentioned. In two of the three cases which I have examined there was not only degeneration, discoverable by the Marchi method, of the whole cortico-spinal neurones, but of the lateral branches which pass off from the axis-cylinder processes to enter the corpus callosum (*vide* Fig. 6). This degeneration of the motor fibres in the corpus callosum strongly favours the primary degeneration theory of the origin of the disease being a nutritional degradation of the neurones themselves independent of external vascular or supporting tissue changes. Moreover, in these cases I have found that the tangential, super-, and inter-radial systems of fibres were intact (*vide* Fig. 7). Now, if it were any external condition these neurones would have suffered with the motor neurones. Senator published a case of typical amyotrophic lateral sclerosis in which there was no degeneration found in the pyramidal tracts. We can only explain the symptoms by supposing that there was interruption between the cortico-spinal and spinal muscular neurones, either a failure of junction between the two, or possibly, in view of the opinion of von Monakow and of the recent interesting observations of Schäfer, an atrophy of intermediate cells (of Golgi) (*vide* Fig. 8). Schäfer is of opinion, based upon observations made by the Marchi method on spinal cords of animals on which he had performed hemisection of the spinal cord, that the fibres of the pyramidal tract do not end in the terminal arborisation around the anterior horn (spino-muscular neurones), but are in connexion with intermediate cells situated at the base of the posterior horn; if this doctrine be true a voluntary motor impulse will pass through three sets of neurones instead of two. There is always a considerable amount of cellular atrophy at the base of the posterior horn in amyotrophic lateral sclerosis, therefore the appearances presented by this disease do not negative this theory.

DEGENERATION OF AFFERENT AND EFFERENT SYSTEMS.

Both afferent and efferent tracts of the spinal cord may undergo degeneration, giving rise to the condition known as "combined sclerosis" which is met with in various forms of grave anæmia and in pernicious anæmia, first thus described by Lichtheim and Minnich, also in ergotism, pellagra, and lathyrism. This degeneration cannot be produced experimentally in animals, and we must suppose that some auto-intoxication occurs by which a progressive degeneration affecting primarily the long tract afferent and efferent systems in the cord takes place. I have had the opportunity of examining microscopically three cases of combined sclerosis with grave anæmia, and I found that the process of degeneration was not limited to the spinal cord. In two



cases which I examined by the Nissl method there were marked changes in the cortical pyramidal cells, and when examined by the Marchi method all these cases showed degeneration in the whole pyramidal system from the cortex downwards, although it was more marked and extensive in the spinal cord than in the pyramid and pons. Likewise, the cells of Clarke's column showed in two cases examined by the Nissl method degenerative changes, and both ventral and dorsal cerebellar tracts were extremely degenerated. The changes, however, in the posterior spinal ganglia were but slight, probably for the same reasons as I have mentioned in referring to tabes.

A valuable paper on Sub-acute Combined Degeneration has recently appeared in *Brain* by Batten, Russell, and Collier. 12 cases are narrated and seven necropsies with microscopical examinations. The authors are of opinion that the disease is a degeneration due to a toxic agent in the blood.

POLYNEURITIS.

Multiple polyneuritis occurs as the result of toxæmia. The poisons which give rise to the condition are numerous, but by far the most common is alcohol, and it is about this that I shall speak more particularly. Alcohol affects not only the peripheral nerves but the brain too, where it produces degenerative changes accounting for the symptoms manifested by the patients during life. A consideration of the extent of surface of the motor and sensory neurones shows that relatively the portions covered with the myelin sheath and sheath of Schwann, as compared with the rest of the neurone, are enormous. For it is obvious that the neurones supplying sensation to the soles of the feet and the motor neurones supplying the muscles of the feet are from three to four feet long, and if we admit that the trophic centres are in the cells of origin at the lower end of the spinal cord, then it is quite obvious that parts so remote from the trophic and genetic centre will suffer from nutritional failure caused by the insidious action of toxic

FIG. 8.

substances such as alcohol. As the effects of the poison become more marked so the functional defect in sensation and movement travel up the legs towards the centres, so that we have in peripheral neuritis an anæsthesia progressing in the manner one puts on a stocking, and as sensation returns in recovery it proceeds as one takes off a stocking, except that there is not a sharp upper border. This would quite accord with the fact that the parts most remote from the centres of nutrition are the first to be affected and the last to recover. Very probably also the parts most remote from the centre of circulation, the heart, are more liable to be affected. Thus, the extremities of the limbs are most affected as regards movement and sensation, and it seems that mineral poisons, arsenic, lead, &c., and alcohol, which are taken into the system for some time before effects are produced, act more particularly on the peripheral nerves. There is very little evidence in these cases of the poison producing interstitial inflammation, neither do we find changes sufficiently marked, as a rule, in the ganglion cells to account for the symptoms. The earliest and most obvious change is a proliferation of the nuclei of the sheath of Schwann, and this condition may be found before microscopical evidence exists of the degeneration of the myelin sheath, as revealed by the Marchi method. This does not, however, show that changes have not taken place in the myelin sheath, for the following reasons. The products of degeneration, we know from experimental section of the nerves, are rapidly absorbed and are by no means so obvious as in the central nervous system. Again, a chemical change may have taken place in the protagon, which has not advanced to a stage in which a non-phosphoretted fat, essential for the Marchi reaction, has been produced. We know that for at least four days after section of the nerve the Marchi reaction is not given, and yet we have no reason to believe that protagon has not been undergoing a chemical change during that period. Again, the nerve fibres are not all affected simultaneously, some fibres being affected more than others. It may be asked, if the poison, which has been accumulating in the system and producing its toxic effects on the nervous system, acts upon the whole neurone, why are changes not seen throughout the whole neurone? and why should the poison not be the effect of irritation of the chain of tubular mesoblastic cells which surround the axis-cylinder process of the neurone? If it were so there is no reason why it should not affect the nerves of all parts of the body equally. I conceive that this proliferation of the nuclei of the sheath of Schwann is due to a disturbance of the normal physiological nutritional interrelationship between the neurone and the cells which ensheath its axis-cylinder process. It is a vital reaction on the part of these cells to the progressive nutritional failure of the neurone which will eventually terminate in destruction of the essential conducting axis-cylinder. In fact, we know that this takes place when a nerve is cut, and it is a provision for repair; therefore it is wrong to look upon this proliferation of nuclei of the sheath as evidence of irritative effects of the poison, but rather as an attempt to repair the destruction caused by the poison.

In three cases of alcoholic neuritis which I have lately examined in conjunction with Mrs. Hamilton Williams, M.B., it was found that many of the nerves did not show very marked evidence of degeneration by the Marchi method; there was, however, considerable nuclear proliferation of the sheath of Schwann, especially marked in the nerves of the lower extremities. In one case in which there was complete paraplegia the ganglion cells of the lumbar-sacral spinal cord showed well-marked chromolytic changes; the Nissl granules in many of the cells of the anterior cornua had entirely disappeared; the nucleus was eccentric and the processes broken off; and some of the cells were vacuolated (*vide* Figs. 9, 10, 11, and 12). Marked degenerative changes were also observable in nearly all the nerves of the limbs by the Marchi method (*vide* Figs. 13 and 14).

From previous experience and from the electrical reactions which the muscles gave during life I should conclude that a great number of the cells would recover under favourable circumstances. The changes in most of the cells resembled rather the condition which one would find after section of a nerve, the reaction phase, mentioned in Lecture II.; in fact, when we consider it, the condition is really very much the same as that produced by section, for the axis-cylinder processes of the sensory and motor nerves have in advanced cases died for a considerable part of their extent, but under favourable circumstances, especially if the poisonous influence be removed and the nutrition of the muscles be maintained by appropriate treatment, there is no reason why, the same as in section of a nerve, regeneration should not take place. The great thing to remember is that the joints should not be allowed to become stiff or the muscles inactive. Passive movements, massage, and galvanism will stimulate the neurones and hasten regeneration, for we have already had abundant evidence to show the important influence stimulus exercises upon the metabolism of the neurones and the degenerating and atrophic effects of non-stimulation. In two of these cases, in which there was marked fatty degeneration of the heart, we found fatty degeneration of the fine myelinated fibres of the vagus (*vide* Fig. 14).

Examination of the brains of all three cases showed a certain amount of atrophy of the tangential systems of fibres, accounting for the dementia which existed in all three cases. There were also changes revealed by the Nissl method in the cortical pyramidal cells, but seeing that there was no degeneration discovered by the Marchi method in the

FIG. 9.

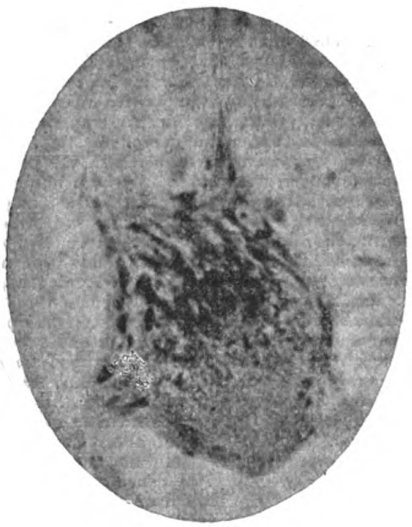


FIG. 10

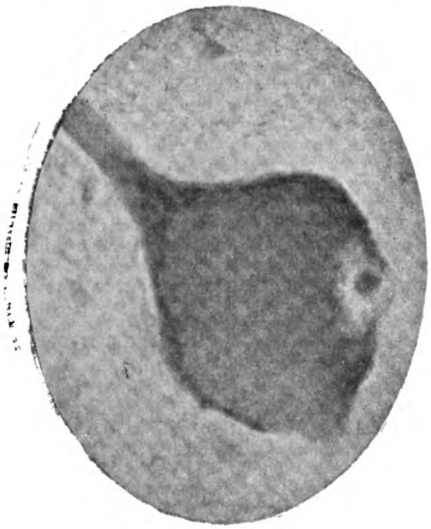

FIG. 11

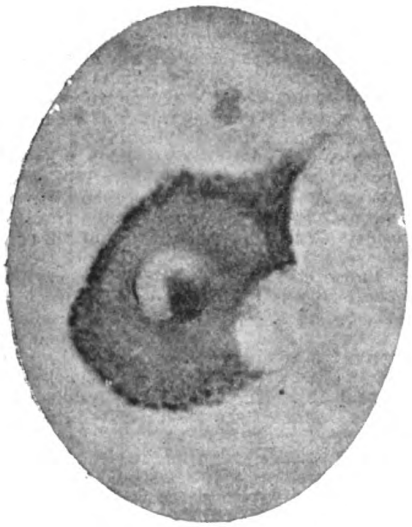

FIG. 12.

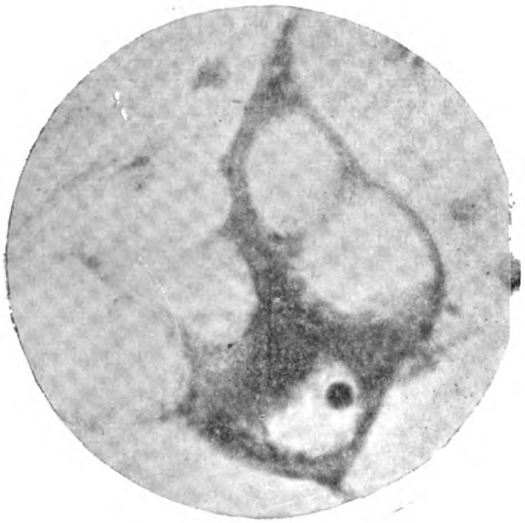

FIG. 13.

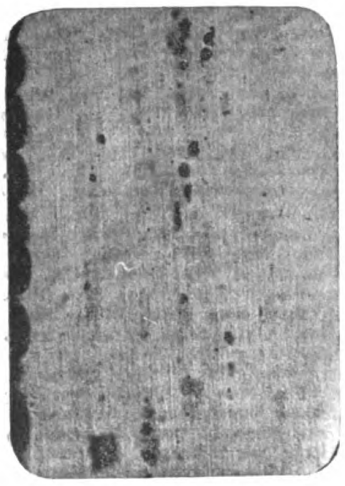

FIG. 14.

spinal cord we cannot assume that these were more than of a functional nature. In one case there were marked congestion and microscopical intra-cerebral hæmorrhages. The condition of the cortex could not be mistaken for general paralysis, for there was not the same overgrowth of glia cells or atrophy, nor was there the same disappearance of Meynert's columns so characteristic of the latter disease.

RELATION OF STIMULUS TO DEGENERATION OF THE NEURONE.

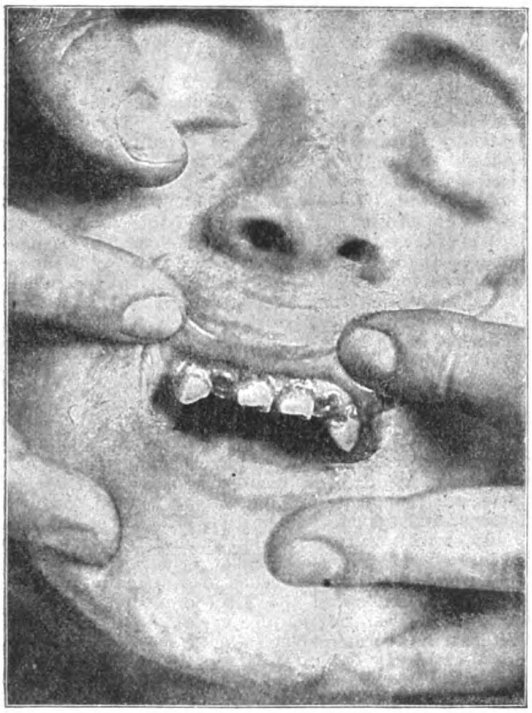
Structure and function are mutually reciprocal and interdependent and we know that a structure which is not used will gradually lose its function, while its nutrition will also suffer and in time atrophy may occur. Consciously and unconsciously a continuous stream of impulses is pouring into the nervous system from without by the sensory channels, which are the avenues of experience and intelligence, and our bodily and psychical life depends upon the existence of such stimuli.

Excess of normal stimulation of itself is seldom the cause of organic disease, although we have examples of psychomotor paralyses in the palsy affecting scriveners, typewriters, pianoforte players, violinists, hammer-men, &c., but whether this is due to an actual degeneration or to a functional depression is not known. If, however, by excessive exercise such a disturbance can take place without any other apparent cause, then undoubtedly stress acting upon structures in a state of nutritional deficiency will lead to a disturbance of the normal physiological equilibrium and a progressive degeneration of those structures which are most remote from the centre of nutrition. Increased functional activity of a part, however, is associated with increased blood-supply, and if the blood contains a toxic substance a larger amount of that toxic substance will be carried to the functionally active part, so that whatever benefit might arise in the way of repair from the additional amount of blood will be neutralised by the excess of poison. Numbers of instances have occurred in my experience in which stress seemed to determine the seat of the degenerative process. I will give a few illustrations. 1. A policeman who was affected with tabes commencing in the arms turned out to be a mounted policeman, and when I pointed out to the students the unusual situation he immediately volunteered the information that the pains began in the arm in which he held the reins. 2. A case of amyotrophic sclerosis affecting a cooper began in the muscles of the right arm with which he wielded a four pound hammer. 3. A man who had alcoholic dementia, paralysis, and wasting of the muscles of the upper extremities, the lower being unaffected, was shown to me as a case of progressive muscular atrophy. I found that he was a porter and the symptoms he presented were determined by his occupation of carrying boxes all day on his shoulders. This patient completely recovered. I will not detain you with a number of further examples, but asylum experience only too well demonstrates the importance of undue mental excitement in causing degeneration of the higher structures of the brain, as in general paralysis. Professor Edinger has emphasised the important influence of stress in determining the seat of nervous degeneration, and his philosophical writings on the subject are worthy of careful consideration; he has, too, endeavoured to prove it experimentally.

Voss was unable to produce degeneration in the spinal cord in rabbits, guinea-pigs, and dogs by injections of pyridine sufficient to produce a severe anæmia; but Edinger repeated these experiments, varying them by inducing stress upon the nervous system by various means, one of which was to place the animals (rats) in a wheel cage. He claims then to have shown: (1) that abnormal stress can produce in animals a degeneration of the posterior columns; (2) that it is possible to produce a predisposition by artificial anæmia by which the influence of stress of much less degree and of much shorter duration can cause this posterior column degeneration; and (3) that this disease stands in close relationship, both as to localisation and cause, to the tabetic degeneration of the posterior columns in man.

RELATION OF HEREDITY TO DEGENERATION OF THE NEURONE.

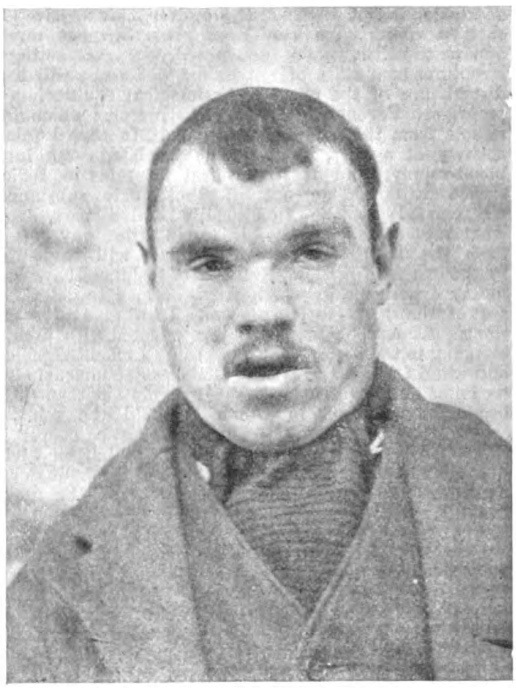
Of all the causes of nervous disease hereditary predisposition stands pre-eminently first. It may be paternal, maternal, convergent, from grandparents, or, according to Weissmann's theory of the continuity of the germinal plasm, there is no limit to the remoteness of the origin of a neuropathic taint. This doctrine must have been known to the high-born Romans who carried the masks of all their ancestors upon public occasions. In fact, in Lucretius it is stated: "Sometimes, too, the children may spring up like their grandfathers, and often resemble the forms of their grandfather's fathers, because the parents often keep concealed in their bodies many first beginnings mixed in many ways, which first proceeding from the original stock one father hands down to the next father, and then from these Venus produces forms after a manifold chance and repeats not only the features but the voices and hair of forefathers; and the female sex equally springs from the father's seed, and males go forth equally from the mother's body, since these distinctions no more proceed from the fixed seed of one or other parent than our face and bodies and limbs. Again, we perceive that the mind is begotten along with the body and grows up together with it and becomes old along with it." The history of the Roman emperors from Julius Cæsar, one of the greatest geniuses the world has seen, but an epileptic, shows how the endeavour to keep the sacred Julian blood for the dynasty culminated under the influence of a depraved environment in the criminal madness of Tiberius, Messalina, Caligula, and Nero. Strictly speaking, it is the tendency to nervous disease rather than the disease itself which is inherited, and this is frequently spoken of as neuropathic or neuro-psychopathic taint. There are, besides, a number of inherited diseases which, although rare, are of great interest, inasmuch as they affect members of a family, the disease frequently commencing in each individual at about the same age. These are termed "family diseases" and include hereditary ataxia (Friedreich's disease), amaurotic idiocy, hereditary chorea, and paramyoclonus multiplex, an interesting family of cases of which I have recently seen. Two boys and two girls were affected with epilepsy and this clonic choreiform spasm of the muscles; in each it commenced at the age of 15 years. There was no direct hereditary history in the parents of any nervous affection, but an uncle suffered from epilepsy. Presumably, therefore, ancestral germinal plasm possessed the neuropathic predisposition, which possibly under some influence which I was unable to ascertain—e.g., some acute specific fever affecting the members of the family or possibly alcoholism or syphilis in the parents—had supplied the contributory factor to develop the disease. In a healthy nervous system we must suppose that the balance of potential is high and that the sense of fatigue is the natural indication for sleep and repose by which nervous energy may be recuperated. The neuropath may be conceived to possess in some portion of his nervous system communities, groups, and systems of neurones, either of defective durability or with an inherited low potential, readily becoming exhausted and especially liable to functional depression, and which under the influence of contributory factors such as toxic conditions of the blood or undue stress undergo premature degeneration. To explain the inherited neuropathic tendency morphologically we may suppose that there is an inherent defect in the germinal plasm which is concerned in the formation of the neurones.



Certain acquired conditions in the parents, affecting them especially at the time of conception, are liable to produce this defect in the germinal plasm; they are acute and chronic alcoholism, syphilis, and tuberculosis. Statistics by Mr. Tredgold relating to 40 cases of congenital imbecility, although not numerous, are valuable because reliable, and in course of time, when he has completed the investigation of this question in all the London county asylums, as he has done at Claybury Asylum, will be of still more value. As far as they go they show that the most important cause of congenital imbecility is inherited neuropathic taint (70 per cent.), generally in some form of insanity,[5] but that alcoholism, syphilis, and tuberculosis are important contributory factors. My own researches on juvenile general paralysis, of which I have now had the opportunity of examining 50 cases, show: (1) that the disease affects both sexes equally; (2) that it may commence at any age from eight to 23 years,[6] according

[5] It is very interesting to note that two of the cases of imbecility with congenital syphilis have become juvenile general paralytics, and in neither of these cases was there a family history of insanity which is independent corroboration of my observations, as neither of these cases are included in my 30 cases.

[6] It is possible that some of the cases occurring in adults in which no history of acquired syphilis can be obtained may still owe the disease to an inherited taint. It is not necessary that they should show external signs of syphilis, for many of the cases which I have recorded were proved to be born of syphilitic parents although manifesting themselves no external signs of disease.



to my statistics; and (3) that in 80 per cent. of the cases there were either undoubted signs or history of congenital syphilis and that in 20 per cent. it could not be excluded. Therefore we may assume that the effect of syphilis on the germinal plasm on one or both of the parents is the essential cause. In the greater proportion of the cases I was unable to obtain a history of insanity or nervous disease in the family, although it was remarkable that in four of the cases and also in one hereditary case of tabes the fathers suffered with general paralysis. The notes of their cases give no evidence of their having acquired syphilis, yet in four out of the five cases there were distinct and well-marked signs in their offspring. From a very careful study of the family histories of these cases I was led to believe that the germinal plasm of the parents, particularly of the father, may be very unequally affected by the syphilitic poison, and it seemed to me that the inherited syphilis was not infrequently the result of spermatic infection only. Many of the mothers never had any illness that they knew of, yet some of their children showed syphilitic teeth, chorio-retinitis, rhagades, and other characteristic signs, while

FIG. 15.

other children appeared perfectly healthy (*vide* Figs. 15 and 16). Generally, however, the history was—miscarriages, still births, syphilitic children, and healthy children in succession. In one family there were three children; the eldest had no external signs of congenital syphilis, but a syphilitic liver was found post mortem. He was an able-bodied seamen, but at the age of 20 years broke down with general paralysis. I consider that this was induced by stress, for he was on duty in the Mediterranean just at the Fashoda crisis and the disease commenced by a fit. The next brother had a characteristic syphilitic nose and teeth but was earning his living as an artisan. The youngest boy is an imbecile in an asylum (*vide* Fig. 16), with characteristic objective signs of congenital syphilis. Another family was interesting in this respect that the eldest daughter of a mother who gave a history of infection showed no signs of syphilis on the body yet died from general paralysis. The next daughter presented well-marked external signs, but at present is healthy otherwise. The majority of the 30 cases gave some interesting details bearing upon this question. Another factor which seemed to have an important bearing upon the occurrence of general paralysis in children of parents suffering with syphilis was the existence of chronic alcoholism in one or both the parents. Thus we see impaired vitality of specialised structures may result from devitalising influences acting upon the germinal plasm of one or both the parents. With regard to the toxic influence of alcohol on the nervous system I have been particularly struck with this fact, that although at least 20 per cent. of the people admitted into the London county asylums yield a history of intemperance as the cause of their mental symptoms, yet I only once remember seeing in the post-mortem room of the asylums a case of well-marked cirrhosis of the liver with ascites. That was in the case of a person celebrated in the police-courts who was convicted nearly 400 times of drunkenness before she was found to be certifiable as incapable of taking care of herself. One must suppose, therefore, that these people who come into the asylum are very susceptible to the toxic influence of alcohol and long before they could drink sufficient to produce cirrhosis of the liver symptoms of alcoholic poisoning of the nervous system arise. In fact, it would rather show that a person who can drink sufficiently long to get a hob-nailed liver has inherited a nervous system of unusual stability. To the mentally unstable alcohol is a poison, and I have been particularly

FIG. 16.

struck with the fact that it acts even in moderate quantities as a poison on women at the climacteric period when potential is low in the nervous system. Another class of individuals often potential to whom alcohol is unquestionably dangerous is the neurasthenic. The sense of fatigue, whether of mind or body, is physiological and protective. It should be responded to by rest; but the active-minded town-dweller who is suffering from nervous exhaustion takes spirits to enable him to make up the deficient energy. He draws, so to speak, a bill on his health which must always be renewed at a higher rate of interest. My own observations and those of Mr. Tredgold, the technical scholar, entirely agree with the observations of numerous authorities who have shown that epilepsy, insanity, imbecility, idiocy, mental weakness, and loss of moral control and will power are frequently the heritage of children born of drunken parents.

DESCRIPTION OF ILLUSTRATIONS.

FIG. 1.—Symmetrical perforating ulcers from a case of tabetic general paralysis.

FIG. 2.—Section of ascending frontal convolution from a case of general paralysis showing engorgement of vessels, disappearance of Meynert's columns from displacement of the nerve-cells, and overgrowth of glia cells.

FIG. 3.—Section of occipital lobe from same case showing practically normal appearance of the cortex. The Meynert's columns are distinctly seen and there are no vascular changes.

FIG. 4.—Case of juvenile general paralysis from which these preparations were made. Photograph shows Hutchinson's teeth and rhagades round the mouth.

FIG. 5.—Described in text.

FIG. 6.—Section of the corpus callosum from a case of amyotrophic lateral sclerosis showing large black degenerated fibres in transverse section.

FIG. 7.—Section of the superficial cortex cerebri of the Rolandic area stained by Marchi-Pal method showing the super-radial and tangential fibres intact.

FIG. 8.—Section of lower portion of grey matter showing absence of large pyramidal cells and replacement by Deiters' cells. This occurred in little isolated foci of the motor area of the cortex.

FIGS. 9, 10, 11, and 12, are photo-micrographs of cells of the anterior horns of the lumbo-sacral enlargement from a case of a woman with severe alcoholic paraplegia with extensive muscular atrophy and degenerative changes in the muscles and nerves of the legs. Magnification 600.

FIG. 9 shows a cell with commencing chromolytic change.

FIG 10 shows a cell with advanced chromolytic change and eccentric nucleus. Both of these cells resemble the appearances presented by cells after section of a nerve and the change may be due to the morbid process having caused destruction of their axis-cylinder process. They, however, are capable of regenerating the axis-cylinder process, the same as may occur after section of a nerve.

FIGS. 11 and 12 show, on the other hand, morphological changes indicating death of the trophic and genetic centre. We see in Fig. 11 a concavity on one side indicating rupture of the nuclear membrane, and in Fig. 12 there is so much vacuolation of the protoplasm of the cell as to indicate its destruction.

FIG. 13 is a section of the external popliteal nerve, stained by Marchi method. The black degenerated myelin is not very abundant because it has in great part been absorbed, but other stains—e.g., Stroebe—show that hardly any healthy fibres exist. This preparation is from the same case as the cells described above. Magnification 200.

FIG. 14.—Section of the vagus nerve from a case of acute alcoholic neuritis with hæmorrhagic encephalitis and dementia. The patient suffered with very marked signs of cardiac failure and died comparatively suddenly. Marked fatty degeneration of the heart was found post mortem. The section stained by Marchi method shows fine medullated fibres undergoing degeneration. Magnification 600 diameters.

FIG. 15.—Case of tabetic form of juvenile general paralysis which died, aged 20 years, three months after onset of symptoms. The photograph shows characteristic teeth.

FIG. 16.—Photograph of congenital imbecile with depressed bridge of the nose. He also had Hutchinson's teeth. A brother who died from juvenile general paralysis showed no such external signs.

THE EXETER DISPENSARY.—A special meeting of the governors of the Exeter Dispensary was held on June 30th under the presidency of Mr. S. Ward, J.P. It was decided to add two medical officers to the staff of the institution and it was further determined that any member of the medical staff who wished to do so should be allowed to limit the number of patients admitted under him on his day to 20 recommends, provided he did not refuse to admit any urgent cases or those of patients coming from a distance. The governor decided that for the future a trained nurse should be appointed to the dispensary. There were six applications for the posts of surgeons and on a ballot being taken Dr. Ransom Pickard and Dr. J. A. S. MacKeith were elected.

ABERDEEN HOSPITAL SATURDAY.—On Saturday, June 23rd, the fifth annual demonstration under this movement took place in what promised to be splendid weather, broken somewhat by a thunderstorm. In the forenoon there was a monster street procession from the reclaimed land north of the river Dee to Duthie Park, the route being by leading thoroughfares, and the parade being taken part in by the various friendly societies in the city, representatives of trades, cyclists in fancy costume, school-children, and others. Collections were made *en route* from the spectators, and at Duthie Park (where a charge for admission was made) an attractive programme of sports, including a brass band competition, was presented. The attendance was very large, but it will be some time before the financial result is made known.

ON THE CONFUSION OF TWO DIFFERENT DISEASES UNDER THE NAME OF RUBELLA (ROSE-RASH).

BY CLEMENT DUKES, M.D., F.R.C.P. LOND.,
PHYSICIAN TO RUGBY SCHOOL; SENIOR PHYSICIAN TO RUGBY HOSPITAL

A SUSPICION of the confusion of two different diseases under the name of "rubella" has been entertained by some of those who have had an extensive experience in the eruptive fevers of the young; but while myself suspecting the fact for several years I failed to attain conviction until the advent of an epidemic in April, 1900. These two diseases are not classified in the third edition (being the second revision), 1896, of the "Nomenclature of Diseases" by a joint committee of the Royal College of Physicians of London, but are included under the single terms of "rubella," "rötheln," "German measles," or "epidemic rose-rash." The purport of the present communication is the establishment of the proposition, on definite and analysed grounds, that two clearly distinguishable diseases exist.

It will be admitted that there is a distinct disease called "measles" (morbilli). It will further be accepted that there exists another definite disease termed "scarlet fever" (scarlatina). Another disease usually, though most unfortunately, described as "German measles" (rubella) is also recognised. I hope to prove to the satisfaction of the profession that this disease does not consist of two varieties of one kind, as I have hitherto contended with the profession in general, but that two definite and separate diseases have been confounded under one name. For the law observed in zymotic diseases prevails here, *that an attack of one of these diseases does not protect from an attack of the other.*

By many members of the profession the diseases hitherto classed under the term "rubella" are considered to be of a very trivial nature. But when one frequently hears thas certain children have had three attacks of measles—that it to say, English measles, German measles, and the disease I am about to describe—none of which affords protection against the remainder, and where one at least is, or is likely to be, confounded with scarlet fever, the question assumes an aspect of grave importance both to the young and to the schools where an important portion of their lives is spent. Precise accuracy in distinctions will thus aid in diminishing the prevalence of zymotic disease and tend to enhance professional credit. It was not until the close of the seventeenth century that, mainly through the researches of Sydenham, scarlet fever ceased to be confounded with measles, and now, at the close of the nineteenth century, rose-rash is still confused with measles and with scarlet fever. Finally, on the verge of the twentieth century, we are only just discovering, and not merely surmising, that a "fourth disease," perfectly distinct from measles, rose-rash, and scarlet fever, is to be distinguished. I will not venture to suggest the appropriate name for this disease. I content myself with referring the question of nomenclature to the Royal College of Physicians of London. But whatever term should be ultimately adopted it should obviously preclude any possible confusion with scarlet fever or rose-rash. Pending this authoritative decision I shall tentatively employ the general expression of the "fourth disease."

The fundamental law in medicine—the science of our practice, ably taught by Cullen more than a century ago but now too frequently ignored—affirms that one attack of an eruptive fever entails immunity from a second attack in the same individual during childhood. The "germs" of infectious disease apparently require a virgin soil for development; a prior attack seems so to exhaust the soil or so to transform it chemically by the products of growth that it becomes incapable of furnishing a suitable nidus for the reproduction of the germs. This law is so permanent (for the insignificant exceptions may be regarded as scientific curiosities only) that for the practical guidance of our work it may be considered an absolute and invariable rule. Each disease, moreover, possesses its own characteristic seed which is entirely *sui generis*. But a curious fact in the life-history of these zymotic diseases, at present inexplicable, is that the growth of some germs in the body appears to produce so vital an alteration in the soil as to facilitate the immediate fertilisation and development of the germs of other diseases.

For example, the concurrence, or sequence, of measles and whooping-cough, of scarlet fever and diphtheria, and of measles and diphtheria is well known, and I have observed the marked influence which influenza has exercised upon the concurrent or subsequent development of influenza and epidemic rose-rash and of influenza and mumps.

The question has also occurred to me whether the "fourth disease" which so closely resembles scarlet fever would tend in a series of cases gradually to develop into true scarlet fever. But I have never observed the slightest indication in this direction. I have always found, as soon as I knew my subject, that each disease bred true. There was a well-expressed line of demarcation between the two diseases, and notwithstanding their close superficial resemblance every case was either the true "fourth disease" or true scarlet fever, and I shall presently show the concurrence of these two diseases in the same epidemic. I no more believe in its indefinite distinction than I do in what is called diphtheritic sore-throat; either a disease is diphtheria or it is not. The difficulty lies in the accuracy of our diagnosis and not in the definiteness of the disease. Nothing, however, can be achieved without the capacity of accurate diagnosis and there are no cases in medicine which at times are more puzzling and require the expenditure of more thought and judgment than the zymotic diseases we are discussing—rose-rash, the "fourth disease," and scarlet fever. Their elucidation has bewildered and misled many of the ablest physicians, to our professional discredit and the detriment of the welfare of schools. Yet they are as separable as typhus fever is distinct from typhoid fever. To mistake rose-rash for measles causes infinite trouble, but constant confusion of this "fourth disease" with scarlet fever involves, even admitting the perplexities of diagnosis, a very serious error, for if the patient be suffering from the "fourth disease" a period of isolation, usually of 14 days, and at most 21 days, is sufficient, notwithstanding the desquamation, which is apparently innocuous, while if the malady be scarlet fever a period of close confinement varying from 42 to 56 days is stated to be required in accordance with our present knowledge. Conceive the significance of this difference in an extensive epidemic—an isolation (two-thirds longer time for each case of scarlet fever) of wholly unnecessary seclusion with all its attendant discomforts, loss of time, and pecuniary cost entailed for medical attendance and nursing. The difficulties may be gauged when errors are committed even by those who have seen a multitude of cases. It requires some courage, I admit, to suspend judgment and plead ignorance when a definite diagnosis is important and urgent; but the admission, when the illness has been erroneously assumed to be scarlet fever, that it is merely this "fourth disease" reaches almost the limit of intellectual and moral candour.

The question has occurred to me repeatedly whether on account of its area, season, and non-fatality the very extensive but non-fatal epidemic of scarlet fever which raged throughout the country in the autumn of 1892 and the spring of 1893 was not really to a large extent an epidemic of the "fourth disease," for it not only occurred to a great extent out of its season but in both cases in which I was consulted by the head-masters of two schools at a distance from Rugby the epidemic proved to be the "fourth disease" (which I then deemed a variety of rose-rash) and not scarlet fever. In one epidemic of rose-rash, however, the whole of the cases will resemble measles. In another epidemic of the (supposed) same illness every case will resemble scarlet fever, as occurred in an entire series of instances in the two schools to which I have referred, comprising 16 at one school and 12 at another. It was epidemics such as these which made me seriously reflect and induced me to institute more searching inquiry into the interpretation of their phenomena. We have also this remarkable fact about rose-rash (rubella) that although (and here there can be no shadow of doubt, since the one affords no protection against the other) it is a perfectly distinct disease from measles, from the "fourth disease," and from scarlet fever, and although rose-rash and the "fourth disease" may be concurrently epidemic, yet rose-rash, like measles, usually affects large numbers, while the "fourth disease," like scarlet fever, always occurs to a much more limited extent, probably on account of its being, again like scarlet fever, less infectious at the onset. In 1894 I wrote that it had been suggested that the disease named "rose-rash" comprised in reality two diseases. In my own mind I had frequently raised the question and had searched for cases in evidence, but I had signally failed to establish a single relevant fact to sustain the hypothesis. Increased observation and extended experience have now, however, convinced me to the contrary.

The great difficulties in the elucidation of the facts which distinguish this "fourth disease" from rose-rash have been these: (1) that similar symptoms to a great extent are present in both diseases, with the exception of the dual appearance of the rash; (2) that in the same patient the eruption of rose-rash sometimes resembles measles at the commencement and terminates by the coalescence of the spots in assuming the scarlet fever eruption (this, however, is quite distinct from the *course* of the rash in the "fourth disease"); (3) that these two diseases—rose-rash and the "fourth disease"—frequently occur in the same locality at the same time; and (4) that the period of incubation is almost identical in both diseases. I shall, however, prove by conclusive evidence—what I have only recently established by the occurrence of an epidemic—that an attack of rose-rash does not afford protection against the "fourth disease" and *vice versâ*. So minutely, again, does this "fourth disease" mimic scarlet fever that I am convinced that innumerable cases are ascribed to the latter which belong to the former, and *vice versâ*. I may add that it sometimes demands a series of cases before a conclusive diagnosis can be arrived at, when the result becomes incontrovertible, although when close and accurate observations are made the difficulties usually resolve themselves.

I shall now specify some of the practical difficulties which arise in the elucidation of this "fourth disease."

I.—I cite an epidemic which was stated to be scarlet fever but which proved to be this "fourth disease."

In the year 1892 the head-master of a public school called me in consultation in connexion with 16 cases of an illness which was supposed to be scarlet fever. After a careful investigation of the cases, some of which were in the first stage and others in the last, I was able to prove to my own satisfaction at all events that the disease was that which I then termed the "scarlet fever variety" of rose-rash (rubella) but which I should now designate the "fourth disease." As a difference of opinion existed the head-master, after explaining the position to the parents, wisely afforded them the opportunity of regarding the ailment as scarlet fever or as this "fourth disease," as they might decide. The only trouble occurred with parents who were medical men, all of whom considered it to be scarlet fever. But I never heard of a solitary instance of scarlet fever appearing in any of the lads who went home for the holidays. I did, however, hear of one of the nurses who, after she had left, suffered from what was diagnosed as a genuine case of rose-rash. Now let us estimate the meaning of this verdict to the affected lads themselves. We will consider the period of isolation alone, without introducing the elements of the anxiety and expense. If these cases indicated the "fourth disease" 14 days' isolation was usually amply sufficient if followed by

complete disinfection. 16 cases × 14 days = 224 days' isolation; 16 cases × 42 days = 672 days' isolation; or a difference of 448 days.

II.—I next refer to an epidemic of 31 cases of an illness (assumed to be the scarlet fever variety of rose-rash, but really this "fourth disease") which proved to be scarlet fever and the "fourth disease" simultaneously occurring. This epidemic conclusively shows the entity of this "fourth disease" as a distinct and definite malady, separable from scarlet fever and even from a modified scarlet fever.

In the year 1893 the head-master of a private school summoned me to a consultation on account of an epidemic amongst his boys which was regarded as the scarlatina variety of rose-rash (rubella). The head-master was a careful, painstaking man who supplied the date of illness of every boy; and the instances finally amounted to some 31 in number. (Table I.) The medical man in attendance also furnished most valuable assistance at my visit. It was a remarkable series of cases, especially as some of the patients (32·25 per cent.) apparently passed through the same illness twice over. I saw every boy affected at the date of my visit on March 9th, 1896, in every stage of the disease. Two of them were seriously ill and eventually died. Though the most careful investigation was made I had the chagrin of confessing that the problem remained unsolved—the most perplexing and anxious problem I had encountered in a long experience.

It was impossible to acquiesce in this preliminary failure and I undertook to return the next day. Meantime I pondered over my clinical notes and light dawned at last. In following out endless hypotheses I was enabled at length to show that there was a malady which commenced on Feb. 4th, 1893, which was followed by seven cases occurring on Feb. 18th and 19th, involving, therefore, a period of 14 and 15 days. On Feb. 24th another case of illness arose, followed by three others on Feb. 26th and 27th, and having therefore a period of incubation of from two to three days. Following this clue the problem was eventually solved the next day, as shown in Tables II. and III.

NOTE.—No. 9 was said to have had scarlet fever previously, but that illness was evidently the "fourth disease," for although the patient was freely exposed to the infection of the "fourth disease" he escaped it and had true scarlet fever. It was this mistaken diagnosis of his former illness which occasioned so much difficulty at the commencement. No. 22 and No. 28 died.

THE DISTINGUISHING CHARACTERISTICS BETWEEN RUBELLA (ROSE-RASH), THE "FOURTH DISEASE," AND SCARLET FEVER.

Rubella (rose-rash).	The "fourth disease."	Scarlet fever.
1. *Premonitory symptoms.*—In many instances none; no headache; no vomiting; no catarrh; no cough; but frequent sore throat. If the attack be severe some malaise, anorexia, and drowsiness will exist.	1. *Premonitory symptoms.*—In many cases none, even with a copious eruption; neither headache, nor vomiting, nor catarrh, nor cough, but frequently slight sore throat. If the attack, however, be severe there may be pronounced malaise for some hours, with headache, anorexia, drowsiness, chilliness, and even considerable backache.	1. *Premonitory symptoms.*—If the attack be slight the patient merely feels tired and usually complains of some amount of sore throat, headache, and chilliness. There may, however, be considerable malaise, with a genuine sense of illness, accompanied by some vomiting.
2. Its *season* is spring and summer.	2. Its *season* is spring and summer.	2. Its *season* is autumn and winter.
3. The *incubation period* is usually 18 days, but with a range of from nine to 21 days.	3. The *incubation period* has a probable range of from nine to 21 days.	3. The *incubation period* is usually from two to three days, but with a range from a few hours to seven days; it very rarely extends beyond the fifth day.
4. The *eruption* is usually the first noticeable symptom. Its appearance is that of minute rosy red dots, not patches. It shows itself first behind the ears and on the scalp and face, especially on the oral circle; from these situations it extends to the neck and the chest and ultimately covers the entire body. The minute dots become larger and gradually coalesce, forming patches of the bat's wing pattern, which so extend and alter in colour as to be indistinguishable from measles.	4. The *eruption* is usually the first noticeable symptom and will cover the whole body with a considerable diffuse rash in a very few hours. The hue is a bright rosy red and the eruption is raised somewhat from the surface of the skin. The sensation of heat of the skin to the touch, even where the rash is very full, is much slighter than in scarlet fever.	4. The *eruption* is diffuse, dusky red, papular in character, and originates behind the ears. It presents a goose-flesh appearance. It does not occur in isolated dots at any stage; nor in patches which are raised and have well-defined margins. It appears early about the clavicles and on the chest and the covered parts of the body. The rash is rarely so full at an early period as in the fourth disease and the skin is markedly burning to the touch.
5. *The throat.*—The fauces look dry, with a dark, motley, red hue.	5. *The throat.*—The fauces are usually swollen and reddish, assuming a velvet appearance, but this condition bears little relation to the extent of the rash.	5. *The throat.*—The appearance of the fauces may vary from the most insignificant affection to an intense dusky redness, with marked swelling, showing sometimes white spots of inspissated secretion; and the severity of the throat affection bears usually a distinct relation to the skin eruption.
6. *The eyes.*—The conjunctivæ are pink red and suffused.	6. *The eyes.*—The conjunctivæ are pink and suffused.	6. *The eyes.*—Normal.
7. *The glands.*—The lymphatic glands throughout the body are enlarged, tender, and hard, like peas, notably the posterior cervical, the axillary, and the inguinal.	7. *The glands.*—The lymphatic glands universally are enlarged, hard, and tender, and feel like peas, though less manifest than in rose-rash. Those mainly affected are the posterior cervical, the axillary, and the inguinal.	7. *The glands.*—The lymphatic glands of the throat and neck can scarcely be detected during the first few days; but subsequently they may be enlarged in proportion to the severity of the faucial affection. This, however, creates no difficulty, as the axillary and inguinal glands are not so involved as in rose-rash.
8. *Desquamation.*—There may, perhaps, be a little branny desquamation, but frequently there is none.	8. *Desquamation.*—The desquamation may be slight, or as complete as possible, even extending to a general peeling of the hands and feet. But the desquamation bears no relation to the intensity of the eruption, for it often happens that a very full eruption may be followed by little or no desquamation, and what does occur disappears in a week or two. On the other hand, a full eruption may be attended by a general peeling as free as in the worst cases of scarlet fever, but mostly in small scales rather than in flakes or sheets. A slight rash is usually accompanied by little or no desquamation. But I have never seen a case of scarlet fever with a full eruption where the desquamation did not occur eventually in sheets, the process lasting many weeks. If a series of cases be observed these abnormalities will be very apparent.	8. *Desquamation.*—The desquamation always bears a ratio to the extent of the eruption. A copious eruption signifies a free desquamation, while a scanty eruption is followed by a sparse peeling, which, however, does not cease for many weeks. It commences invariably by a peeling of the tongue on the fourth day, which extends to the lips and is followed by peeling of the face and behind the ears; one of the easiest places in which to detect the desquamation early is the ear. The desquamation occurs in pieces or shreds rather than scales, and is very free about the hands and feet, lasting for many weeks. At the commencement of the peeling circles of desquamation are formed around the raised papillæ, though I have once seen this state in the fourth disease where the peeling was excessive.
9. *The kidneys.*—They are rarely affected and then only with a trace of of albumin.	9. *The kidneys.*—Rarely affected. Where they are involved the condition is probably that only of the albuminuria of adolescents.	9. *The kidneys.*—Albuminuria is very frequent. The liability to acute nephritis is very decided unless the treatment be appropriate.
10. *Sensations of illness.*—Even with a full eruption as intense as in measles the patient usually states that he does not feel ill, although there may be other indications to the contrary.	10. *Sensations of illness.*—Where the eruption is slight there is no illness of any kind, and where the eruption is copious the feeling of illness is sometimes scarcely apparent, although I have seen boys really ill from this disease.	10. *Sensations of illness.*—In slight cases there is no apparent illness, but I have never seen a case with a severe eruption where the patient was not really, and also sensibly, very ill.
11. *The tongue.*—It is clean or slightly furred and never coated with a thick, white fur, which peels on the fourth day.	11. *The tongue.*—The tongue is clean or slightly furred and never coated with a thick white fur, which peels on the fourth day, leaving the tongue raw.	11. *The tongue.*—If the case be slight there may be no early signs, but in a well-marked case the tongue is coated with a thick white fur which, peeling off from the tip and edges on the fourth day, gradually leaves a raw red tongue, commonly termed the "strawberry" tongue.
12. *The pulse.*—It is normal or slightly increased in frequency, but always bearing a ratio to the temperature.	12. *The pulse.*—In slight cases it is normal and where the case is a well-marked one the pulse is quickened, but bears a ratio to the temperature; that is to say, where the pulse is accelerated the temperature is raised in a proportionate degree.	12. *The pulse.*—Even in slight cases the pulse is accelerated and in severe cases very greatly quickened and always out of all proportion to the height of the fever; that is to say, even with a temperature only just above normal (99° F.) the pulse will be very rapid (120).
13. *The temperature.*—This varies from normal to 103° or 104° F.	13. *The temperature.*—This varies from 98·4° to 103° or 104° F.; but even with a very extensive rash the temperature is not necessarily high.	13. *The temperature.*—This varies from 99° to 106° F., but is never increased in the usual ratio to the pulse. A full rash always means a high temperature.
14. *The course of illness.*—The symptoms, however severe, disappear in a few days, leaving comparatively little feeling of illness; where the eruption is slight there may be no illness whatever.	14. *The course of illness.*—The symptoms, however severe, pass off in a few days, leaving comparatively little feeling of illness.	14. *The course of illness.*—The illness gradually subsides in from four to seven days. Desquamation commences as eruption fades and continues for from six to eight weeks or more, and lasts longest on the hands and feet.

THE DISTINGUISHING CHARACTERISTICS BETWEEN RUBELLA (ROSE-RASH), THE "FOURTH DISEASE," AND SCARLET FEVER—(*Continued*).

Rubella (rose-rash).	The "fourth disease."	Scarlet fever.
15. *The period of infection.*—I do not know any illness which is so infectious in its earliest stage, even before any symptoms are manifest. It results from this cause that schools suffer to so great an extent from the disease when once it has found an entrance. It is less infectious in its later stage.	15. *The period of infection.*—It is not so very infectious in its earliest stage. In its later stage, even while desquamation is taking place, it is not infectious beyond two or three weeks after thorough disinfection.	15. *The period of infection.*—This disease is the least infectious of any illness during its early stage. It therefore allows time for quarantine and isolation and thus can be controlled, so that an epidemic may be prevented more readily than in any other infectious illness. After the first 48 hours the infection is very powerful, but I am not prepared to pronounce upon its duration. Until this can be ascertained the only safe rule is the assumption that it may last as long as desquamation itself, although I am quite clear that this is inaccurate.
16. *Protection.*—The attack affords no protection against measles, the "fourth disease," or scarlet fever.	16. *Protection.*—The attack affords no protection against scarlet fever or rose-rash.	16. *Protection.*—An attack affords no protection against the "fourth disease" or rose-rash.
17. *The duration of infectiveness.*—From 10 to 14 days where efficient disinfection is in force.	17. *The duration of infectiveness.*—From 10 to 14 or even 21 days where efficient disinfection is in force.	17. *The duration of infectiveness.*—From six to eight weeks or more—i.e., when the desquamation has ceased. But I am far from believing that the infection lasts so long after efficient disinfection, though at present I can adduce little proof.
18. *Sequelæ.*—Practically none.	18. *Sequelæ.*—Practically none, but I have seen the submaxillary glands enlarged.	18. *Sequelæ.*—Nephritis; suppuration of the submaxillary lymphatic glands and others; otitis; rheumatism; endocarditis.
19. *Termination.*—Usually complete recovery in a fortnight.	19. *Termination.*—Usually complete recovery in a fortnight.	19. *Termination.*—Usually complete recovery ensues, but sometimes a prolonged convalescence on account of the sequelæ; but the disease shows a high mortality in the very young.
20. *Treatment.*—The patient requires about five days in bed, followed by three days indoors; then about six days in the fresh air; and after complete disinfection he may safely mix with others. *Abortive* cases of rose-rash are frequent and are responsible to a large extent for the spread of this disease. The difficulty is to grasp them, as no actual illness occurs. 1. *Pink eyes.*—There is a group of cases of epidemic roseola which have no symptoms that I have yet ascertained except pink conjunctivæ. And these cases, while capable of passing the illness on to others, are immune against a subsequent attack themselves. 2. There is another group of cases of epidemic roseola which I believe—but I cannot at present advance beyond belief, for I have not yet satisfied myself by actual proof—may occur without showing any symptoms beyond slight feverishness and enlargement of the lymphatic glands throughout the body.	20. *Treatment.*—The patient may be permitted to get up on the fifth or sixth day or as soon as his strength permits, irrespectively of the desquamation and without danger from sequelæ. He then requires three or four days indoors followed by five or six in the fresh air, and may safely join his schoolfellows at the end of from 14 to 21 days, notwithstanding desquamation, provided the disinfection has been thorough.	20. *Treatment.*—Every case of scarlet fever, however slight, requires 21 days of absolute confinement to bed. The patient should be clothed in a flannel night-shirt and the skin daily greased with carbolic or eucalyptus oil. No food should be given for the first week except milk and farinaceous food, however mild the illness, in order to guard against nephritis. The patient should not be permitted to join his friends for six or eight weeks, but I do not think it essential to isolate cases until all desquamation has ceased from the hands and feet, for this process sometimes occupies several additional weeks. I have acted on this assumption for many years without harm, even transferring boys to their own homes. Of course, complete disinfection is imperative.

The above analysis (Tables II. and III.) of this remarkable epidemic conclusively shows: (1) that two distinct infectious diseases were existent in the school at the same time; (2) that these diseases were scarlet fever and what I then termed the scarlet fever variety of rose-rash, but in reality this "fourth disease"; and (3) that the "fourth disease" commenced on Feb. 4th and the scarlet fever on the 24th.

I was further able to discriminate, mainly guided by the periods of incubation, as well as by the existing and the pre-existing symptoms: (1) that some boys had scarlet fever only; (2) that others had the "fourth disease" only; (3) that one had scarlet fever and subsequently the "fourth disease"; and (4) that others had the "fourth disease" followed by scarlet fever.

The satisfaction of unravelling so very intricate a problem was marred by the deaths of the two boys (No. 22 and No. 28) I have mentioned above from scarlet fever.

Since this epidemic I have had another instance of this "fourth disease" in a boy who had previously suffered from scarlet fever in 1894.

CASE 32.—A boy, aged 14 years, was isolated on June 2nd, 1900. Sore-throat and rash appeared on June 3rd. The throat was swollen and velvety. The tongue was furred but not coated. A copious rash ensued which became brick-red as it faded. No desquamation of the tongue or skin occurred, though the latter was rough. The posterior cervical glands were very tender and enlarged. The maximum temperature was 100·4° F., and the maximum pulse was 84. There were, therefore, two cases of the "fourth disease" out of 32 (6·25 per cent.) who had previously had scarlet fever. This epidemic proves incontestably that, besides scarlet fever, there is another malady, which I have provisionally named the "fourth disease," and that the one affords no protection against the other.

III.—The following facts connected with an epidemic of this "fourth disease," where 42·1 per cent. of the patients had already suffered from rose-rash (rubella), demonstrates its distinctive character and consequent classification.

This epidemic occurred at Rugby—commencing on March 13th, 1900, and terminating on April 1st, 1900—and it affected 19 boys. The illness resembled scarlet fever more closely than any other series of cases I had yet seen, due not only to the marvellous resemblance between the rash and that of scarlet fever, but also to the copious desquamation of the skin which in some instances succeeded. It was clearly, however, an epidemic of the "fourth disease" alone. In this series 42·1 per cent. had already suffered from rose-rash (some within the preceding 12 months), so that it was evident that these diseases were different and destitute of mutual protectiveness. On April 3rd the school dispersed for the vacation and each parent was advised that, notwithstanding the resemblance, the malady was not scarlet fever. I only heard of one case occurring during the vacation which was diagnosed as scarlet fever; but one parent—a medical man—whose two sons were at the school suffering from this "fourth disease" was so convinced when he saw them that this malady was scarlet fever that he desired me to keep them in bed, to avoid feeding them, and to examine their urine daily, which I had done, I need scarcely add, in every instance. On May 12th this gentleman addressed to me this exceedingly kind and handsome letter: "I feel I ought to write and thank you,

as a parent, for the firm and correct stand you took about the cases of our boys last term. It required not less courage than knowledge to stand out against the temptation to call those cases scarlet fever and to involve many parents and friends in a prolonged period of anxiety and considerable expense. This was especially so with our boys, both of whom had had German measles (rubella). Our younger son at Rugby desquamated, as you know, as freely as any scarlet fever case and continued desquamating for six or seven weeks. The elder had just a little on the soles of his feet after five or six weeks. They mixed freely with others, including our little boy of three and a half years of age, soon after their return from Rugby."

I append some few notes of the cases and I confess that I never observed such extensive peeling except in scarlet fever, but it is a curious fact, and one that may prove of value, that the two boys who desquamated most had in past years suffered from general eczema and had naturally a rough dry skin.

I now furnish a brief *résumé* of the 19 cases of this series.

1. *Premonitory symptoms.*—There were practically none and no boy admitted illness until the rash appeared, but on inquiry admission of general malaise was elicited.

2. *Vomiting.*—In Case 49 free vomiting occurred in the night and a very full rash was discovered in the morning. This vomiting arose, however, from his having eaten freely of sweets in the evening, which probably disagreed with him as the disease disclosed itself. But as the vomiting was severe and the rash very marked indeed I made a full investigation and watched throughout for evidence of scarlet fever. The maximum temperature throughout his illness was only 99·6° F.

3. *Eruption.*—Really the first symptom to attract the attention of the sufferer was the rash which in nearly every case was very full and quite characteristic of scarlet fever. In fact, if ten experts had inspected the skin and made no other investigation all would have diagnosed the eruption as that of scarlet fever.

4. *Throat.*—The fauces were red and swollen, but occasioned so little discomfort that complaint was rarely made, and the condition was only discovered on inquiry or inspection. However severe appeared the eruption—and in many cases it resembled the worst eruption in scarlet fever—the throat did not assume anything like the same condition as is so usual in scarlet fever.

5. *Desquamation.*—In some cases the skin became merely rough; in most instances there was free desquamation of small scales; while in others the peeling was equal to the worst I have ever noticed in scarlet fever. In Case 34 the skin was detached in large pieces in certain regions; for instance, in the groin and front of the abdomen it peeled off in sheets. Desquamation lasted six or seven weeks. This boy had naturally a rough dry skin and had previously suffered from general eczema. In Case 35 an extent of desquamation occurred which rarely takes place even in scarlet fever. It was detached in sheets from the whole of the body and the toes shed their skin like the finger of a glove in one piece; the heel also peeled almost in one piece and certainly an area of more than an inch square was detached at once. The pieces had to be cut off, as they caught in the bed-clothes and caused pain where the skin was adherent. In Case 39 the skin peeled from the toes in pieces of the size of a shilling and elsewhere in scales. In this "fourth disease" the desquamation bears no relation to the intensity of the eruption; several of these cases with the fullest and intensest eruption were followed by very scanty desquamation. The peeling may continue as long as in scarlet fever although it is apparently innocuous.

6. *The tongue.*—The tongue was furred throughout, which cleaned as all furred tongues do. In no case did the tongue peel on the fourth day, as is so pathognomonic of scarlet fever in both mild and severe attacks.

7. *The glands.*—The lymphatic glands universally were enlarged, hard, and tender, sometimes excessively tender, as in Case 32, but I do not think that they are so markedly affected as in rose-rash. My experience is that the lymphatic glands are always enlarged and tender whenever a copious eruption occurs on the skin from any disease.

8. *Temperature.*—The average temperature was 101° F.; but it ranged from 99·4° to 104·2°. This last temperature occurred in Case 45 where the eruption was scanty, with merely a red, swollen, velvety throat, though the posterior cervical glands were very large and tender. The temperature almost invariably became normal on the third or fourth day.

9. *The pulse.*—In no case, except in Case 45, did it reach 100—a signal contrast to the accelerated pulse of scarlet fever.

10. *The kidneys.*—In no instance did albuminuria arise, although all the sufferers, except the two sons of the medical man I have mentioned, were fed freely as soon as the slight fever (which occurred from the third to the fifth day) had disappeared, and the boys were removed from bed as soon as the rash had subsided, notwithstanding the desquamation.

11. *Incubation period.*—This I was unable to ascertain in the present series of cases, since several of them occurred simultaneously, and I could not discover any connecting links between the sets. My impression is that the illness originated in a boy who was attacked very slightly and who, without my seeing him, continued in his work with it the whole time. I shall hope to ascertain this fact more accurately in some subsequent series. The incubation varies, I believe, from nine days to 21 days.

12. *The duration of infectiveness.*—This lasts from 10 days to 14 days or even 21 days, where efficient disinfection is in operation. The continuation of desquamation is apparently of no moment as a cause of infection or sequelæ.

13. *Previous scarlet fever.*—Previous scarlet fever had not occurred in any instance.

14. *Previous rose-rash.*—Eight boys had already suffered from rose-rash out of this series of 19 cases, or 42·1 per cent.

Since this last series of 19 cases (33 to 51) I have seen one patient (aged eight years) in a private residence (Case 52). This lad developed the malady on June 1st, 1900, when he had suffered from rose-rash, which was prevailing at his school, in January, 1900, so that in 20 consecutive cases of the "fourth disease" nine (or 45 per cent.) had previously had rose-rash (rubella) which is reasonably conclusive evidence that they are two different diseases (Table IV.). Further, it is this malady which, mistaken for scarlet fever, accounts for the prolonged period of incubation which is assigned to the latter disease by some authors; while, on the contrary, it cannot be too emphatically affirmed that the period of incubation of scarlet fever is usually two days, rarely exceeds five days, and never extends beyond seven days.

I conceive that I have now adequately proved that a definite disease exists which I have temporarily designated the "fourth disease." For I have shown:—

1. That although its resemblance is so close to scarlet fever in many features it cannot possess any affinity with that disease inasmuch as both diseases occurred concurrently in the same epidemic.

2. That some of the sufferers had both diseases in the same epidemic.

3. That one patient had scarlet fever followed by the "fourth disease."

4. That several had the "fourth disease" followed by scarlet fever.

5. That although the "fourth disease" has been confused with rose-rash and regarded as a mere variety of rubella, this conclusion is fallacious, since nearly one-half the cases in an epidemic had already had rose-rash within a year or two, which, according to Cullen's established law, is incredible.

6. I have purposely refrained from attaching a name to the disease in order to avoid the anomalous description of the same disease under an indefinite number of terms, as in the case of its ally, which has been variously designated as "rubeola notha," "rötheln," "rubella," "German measles," "epidemic roseola," and "rose-rash." The distinguishing features of rubella, of the "fourth disease," and of scarlet fever will be found in the appended tables.

Rugby.

NEW WORKHOUSE INFIRMARY FOR MERTHYR TYDVIL.—The new workhouse infirmary for Merthyr Tydvil is now completed and is occupied by the patients. The female wards contain 42 beds and there is also a lying-in ward of 10 beds. The men's wards provide accommodation for 70 beds. The expenditure has been over £13,000, exclusive of the furnishing, which amounted to £1300. Mr. Preston Thomas, one of the inspectors under the Local Government Board, at a recent meeting of the Merthyr Board of Guardians congratulated them upon the fact that their infirmary was one of the finest in Wales.

A NOTE ON THE RESULTS OBTAINED BY THE ANTI-TYPHOID INOCULATIONS IN THE BELEAGUERED GARRISON IN LADYSMITH.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

BY the kind permission of Surgeon-General Jameson, M.D., C.B., I am enabled to publish the following officially collected statistics with regard to the results obtained by the anti-typhoid inoculations in the military garrison during the siege of Ladysmith.

TABLE I.—*Results obtained by the Anti-Typhoid Inoculations in the Case of the Officers and Men of the Military Garrison during the Siege of Ladysmith.*

—	Number under observation.	Number of cases of enteric fever.	Proportion in which attacks stand to total number of men in group.	Number of deaths from enteric fever.	Proportion in which deaths stand to total number of men in group.	Proportion in which deaths stand to total number of attacks in group.
Not inoculated	10,529	1489	1 in 7·07	329	1 in 32	1 in 4·52
Inoculated ...	1,705	35	1 in 48·7	8	1 in 213	1 in 4·4

In addition to the above summary of results, obtained on officers and men combined, the figures relating to officers separately are also given in the official statistics. With regard to these last it may be pointed out that quite apart from the fact that these figures relate to a very small group of persons (44 in number) the figures considered as statistics are probably fallacious owing to the fact that the group of inoculated officers (consisting as it must have done almost exclusively of young men at the most susceptible age) is compared with a group of officers which includes all the older and less susceptible men and the men who have already had typhoid fever. The figures referred to are none the less subjoined with a view to conforming to the arrangement adopted in the official statistics.

TABLE II.—*Results obtained by the Anti-Typhoid Inoculations in the Case of the Officers of the Military Garrison during the Siege of Ladysmith.*

—	Number under observation.	Number of cases of enteric fever.	Proportion in which attacks stand to total number of men in group.	Number of deaths from enteric fever.	Proportion in which deaths stand to total number of men in group.
Not inoculated ...	171	43	1 in 4	5	1 in 34·2
Inoculated	44	9	1 in 5	2	1 in 22

In drawing inferences from the figures in this table it is to be borne in mind that the erroneous inclusion or exclusion of a single case, or a difference in the event in the case of any patient included in the category of the inoculated, would sensibly alter the present aspect of the table.

The same circumstance must be borne in mind in connexion with any attempt to base a comparison of the case mortality in inoculated and uninoculated upon the figures in Table I. For it will be manifest that in no circumstances can an estimate of case mortality be safely based on a series of only 35 cases, and least of all would it be permissible to do this under conditions such as those of Ladysmith during the siege, where many other factors in addition to the severity of the attack must have determined the favourable or unfavourable event of the cases. It would, however, appear probable, in view of the figures given in the table, that the case mortality was not influenced by the inoculation. On this subject further light must be awaited, especially as it would appear from certain statements which have emanated from the seat of war that the disease generally runs a milder course in the inoculated.

The question of case mortality is, however, quite subordinate in interest to the question as to how far the figures presented in Table I. enable us to estimate in quantitative terms the reduction in incidence and mortality which can be achieved by the process of anti-typhoid inoculation.

To answer this question it will be necessary to inquire, on the one hand, whether there were any circumstances other than inoculation which may have tended, either to diminish the incidence of typhoid fever among the inoculated in Ladysmith, or unduly to swell the roll of typhoid fever among the inoculated.

In connexion with the former question the only point which comes up for consideration is the question as to whether the inoculated were more favourably circumstanced in the matter of the sanitation of their camps than the uninoculated. No detailed data for the determination of this question are at present available. But this will be seen to be unimportant, in view, first, of the fact that there was in each regiment and corps an uninoculated majority who must equally with the inoculated have benefited or suffered from the sanitary or insanitary condition of the various camps; and, secondly, of the fact that the inoculated who were attacked were drawn from 12 different corps and regiments. It may therefore be assumed that the inoculated and uninoculated were equally exposed to the risk of infection.

The question as to whether there were any circumstances which tended unduly to swell the roll of typhoid fever among the inoculated is one which requires to be treated at somewhat greater length. The following points must be kept in view:—1. So far as is known the men who are set down as inoculated were with hardly an exception only once inoculated. It seems probable from the fact that only two cases among twice inoculated persons have as yet come to my knowledge that second inoculation confers a considerable additional protection. 2. It is possible that certain of the officers who are set down as inoculated may have been inoculated with anti-typhoid serum and not with a vaccine consisting of a sterilised typhoid culture. Two or three instances have been reported to me where this error was committed in the case of officers proceeding to South Africa. In the statistics now in question the date and place of inoculation are in the case of five out of the nine officers attacked set down as unknown. 3. It is possible in the case of the men as distinguished from the officers that re-vaccination against small-pox, which, like anti-enteric inoculation, was in many cases carried out on board the transports may in certain instances have been confused with the latter inoculation. Instances of this confusion have already several times come to my knowledge. 4. Lastly, it is possible that owing to the exigencies of military service or owing to other reasons the full prescribed dose of typhoid vaccine may not in all cases have been injected. Instances of the employment of the vaccine in fourfold reduced doses have come to my knowledge. It is conceivable, but there is nothing either to support or rebut the suggestion, that some reduction of the dose may have been found necessary in the case of the Liverpool Regiment, which was inoculated (presumably, as in the case of other regiments, only very partially inoculated) at Ladysmith on the eve of the outbreak of hostilities. At any rate, it is noticeable that this regiment furnished 13 cases of enteric fever among the inoculated men, whereas the whole rest of the garrison of Ladysmith furnished only an equal number of such cases.

In view of the above points, regarding which there is not at present any information available, it is at present impossible to determine precisely to what extent the inoculated were protected by inoculation. But the results set forth in Table I. would appear to be distinctly encouraging, inasmuch as they show that the proportion, on the one hand, of attacks, and on the other hand of deaths, from typhoid fever was seven times smaller in the inoculated than in the uninoculated. And it may be borne in mind that if the number (no doubt a considerable one) of men who had previously suffered from typhoid fever had been subtracted from the number of the uninoculated, as might quite legitimately have been done, the statistics would have borne an even more favourable aspect.

Netley

ILLUSTRATIONS OF VASECTOMY OR OBLITERATION OF THE SEMINAL DUCTS RELATIVE TO HYPERTROPHY OF THE PROSTATE AND BLADDER ATONY.

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

WHEN sufficient grounds were furnished for asserting that the nutrition and growth of the prostate whether normal or hypertrophied might be importantly influenced by obliteration of the seminal ducts or by removal of the testes[1] the first stage may be said to have been reached in a series of observations which will probably prove of increasing value in practical surgery. Though experience is not yet sufficiently ripe upon this point there are good reasons for believing that a vasectomised or castrated male is not liable to undergo hypertrophy of the prostate in the ordinary acceptation of the term. As this point, as now seems probable, becomes more fully determined not only will a fact of great pathological importance be established, but it will be possible to indicate how by means of a simple and safe operation one of the most serious troubles of advanced life may be averted or controlled. I have reserved for this paper some illustrations of vasectomy or, more strictly speaking, of obliteration of the seminal ducts by torsion, as described in my last articles,[2] in its application to the treatment of prostatic hypertrophy. Statistical information gathered from the mere collection of a number of cases having but little in common is not of much assistance in a matter of this kind where the conditions and circumstances are so varied. In taking my results of vasectomy I find they permit of being grouped as follows: First, where the effects are known to have been good, sufficient, and enduring; secondly, where they have been good but restricted to certain conditions; and, thirdly, where they are alleged to have been inadequate or negative. The question of mortality arising from the operation is not one requiring consideration, as in the series of over 100 cases referred to previously[3] I stated that I have never seen harm follow.

The first group may be said to include cases of prostatic obstruction pure and simple without any other structural complication. Here the bladder is in no sense secondarily implicated structurally and is capable on the removal of the obstacle in front of it of both holding and expelling its contents. It is in this class of cases that shrinkage of the enlarged prostate, however induced, speedily leads to the restoration of the function of micturition in the fullest sense of the term. This group is best illustrated by cases where for some special or pressing reason the obliteration of the vasa was brought about at an earlier period in the history of prostatic obstruction than is usual. Hence this group is less numerous than the succeeding one where catheter life or the systematic use of this instrument had been resorted to previously. The following cases are selected.

A man, aged 68 years, who was seen in 1896, was suffering from the ordinary symptoms of enlarged prostate—namely, frequent micturition, more especially at night, some degree of residual urine, and occasionally incontinence, the diagnosis being confirmed by rectal examination. He had been advised to use a catheter but could not do so conveniently as he had lost an arm. Double vasectomy was performed, with an interval of 10 days between each section. I saw him nearly three years afterwards; the prostate was reduced in size. He was quite well and had no occasion for the catheter.

About the same time I divided the vasa of a man, aged 65 years, whose work was greatly interfered with by frequency of micturition due to enlarged prostate. He also had been advised to use a catheter. He was treated in the same way as the patient in the preceding case with a similar result and was examined 18 months afterwards.

In 1897 I saw a man, aged 65 years, who in the course of his occupation travelled much by railway and otherwise. He had an enlarged prostate and much frequency of micturition for which he was advised to use a catheter. As this meant giving up his livelihood vasectomy was practised with good results and 18 months afterwards he reported himself as being quite well without requiring the catheter.

Early in 1898 I saw a patient in consultation in whose case it had been necessary to tie in a catheter for retention of urine caused by a large prostate. This was so intolerable to him that I suggested vasectomy, which was performed. I have heard on several occasions that he still remains in good health and is able to urinate normally. Six months after the operation I found the prostate much reduced in size.

In 1893 I operated upon a man, aged 67 years, for stone by litholapaxy. There was also some enlargement of the prostate. He remained well till 1897 when symptoms of considerable enlargement developed, and though he had no recurrence of stone he gradually became entirely dependent upon the catheter and was liable on slight provocation to attacks of cystitis and epididymitis. The frequent use of the catheter greatly interfered with his capacity and desire for an active outdoor life and he was compelled to give up hunting and other exercises. In 1898 I divided both his vasa in the usual way with the result that his prostate symptoms gradually disappeared and he resumed his hunting during the whole of last winter as he had previously done. He was able to give up his catheter, using it once in the 24 hours for washing out. He had accustomed himself to the latter as a precautionary method against stone, and though the process, he admitted, was hardly necessary he did not like to give it up.

This appears to be the first published series of cases of prostatic hypertrophy treated by operation in which the object of preserving the normal function of micturition as opposed to an artificial one as illustrated by what is known as catheter life, has been successfully demonstrated. Before leaving this group I would observe that in every case it was explained that the section or division of the vasa might interfere with sexual possibilities. It may, I think, be claimed that in all these instances, and in others that might be mentioned, whatever influence, if any, was exercised on the sexual act the natural function of micturition was preserved to the person operated on and the necessity for the permanent use of a catheter averted. When any question has arisen under these circumstances, so far as my experience goes, relative to whether the urinary or the sexual function should receive first and paramount consideration it has invariably been decided by the patient in favour of the former.

I pass to the second group of cases where I have described the effects following as being good but restricted to certain conditions. These include instances where structural changes in the bladder have supervened upon prostatic obstruction and where catheter life, or the necessity for it, has been more or less developed. This group provides by far the greater proportion of cases to which this class of operations has been recently applied. In a previous paper[4] I showed that there were certain structural effects which followed in the wake of prostatic and other forms of obstruction to the escape of urine by the natural passage which were irrecoverable from. These have reference to the bladder as a reservoir capable of self-expulsion. Hence in the consideration of the class of operations of which vasectomy is a type cause and effect must not be confused. The prostate may be rendered in these ways incapable of obstruction any longer, but this by no means implies that the bladder can be made to expel. And yet the realisation of the former by these means has in this way proved in many instances, which I will proceed to illustate, an inestimable boon.

In November, 1895, I operated on a man, aged 70 years, with a very large prostate and increasing difficulty in catheterism which sometimes required hot baths and opiates before it could be effected. He had shaky hands which increased the difficulty. I advised a double vasectomy. 12 months after this he wrote to me: "I certainly am very much better than I was before the operation, and so long as I am quiet and able to carry out my regular treatment I get on very comfortably."

Another case was that of a man, aged 75 years, with a very large prostate and increasing difficulty in passing his instrument. Double vasectomy was performed in 1898. He soon found that he could pass his catheter quite easily and he again wintered abroad last year with much comfort. He had been previously obliged to forego this change by reason of catheter difficulties.

A man, over 60 years of age, whom I saw in consultation

and in whose case I advised vasectomy for enlarged prostate with frequent attacks of epididymitis which confined him to bed, has entirely got rid of the latter painful complication by the obliteration of his ducts and is now again in the active practice of his profession.

The next case to which I shall refer is an instance of the application of vasectomy as an adjunct to other surgical purposes. It was that of a man, aged 70 years, whom I operated upon for stone in the bladder in 1893. The prostate was so large that I had unusual difficulty in performing the ordinary operation of litholapaxy, and after removing a considerable portion of the stone in this way I had to abandon it without effecting a complete removal of the calculus. The patient, however, did well and was much relieved. In the meantime I divided both vasa and after six weeks' interval I repeated the crushing operation. The considerable shrinkage that was thus effected in the size of the prostate rendered this proceeding easy and complete.

For the relief of hæmorrhage arising out of difficult catheterism in connexion with prostatic obstruction vasectomy has been adopted with good effect in rendering the process easy and avoiding bleeding. This is only to be expected as the result of a process which is generally admitted as reducing the blood-supply to the parts involved. Painful catheterism arising from spasm and tension as the instrument enters the prostatic urethra may be usually relieved in this way by the general shrinkage and relaxation of the gland that follows section of the vasa. I have had several illustrations of this. For reasons such as are here illustrated and for others that might be added to the group the obliteration of the vasa has proved of much service, though the voluntary and natural powers of the bladder may have either not been restored, or have been but partially restored. Easy and safe catheterism has in this way been substituted for that which previously was painful if not also dangerous.

I will conclude with a notice of the third group of results of vasectomy, which seems to me to include the most interesting and suggestive of the series that I have here brought under notice. I refer to those instances where the results are alleged to have been, or seem to have been, inadequate or negative.

For the purposes of this paper I have made numerous inquiries by letter, in addition to other sources of information, from patients who have undergone vasectomy since 1893, when I commenced to practise it with some frequency. Amongst these is a man, now aged 81 years, upon whom I performed double vasectomy for prostatic enlargement of some years' standing early in 1897. On writing to me he informed me that he did not think that he had derived much benefit from this operation. The history of his case, however, will hardly bear out this statement. The patient had been under my observation for four years previously to this. He had considerable irritation and spasm, for which the catheter was being constantly employed. There was also so much cystitis that I then drained his bladder by the perineal route with temporary benefit. In 1896, however, his condition in these respects became worse and the bladder became very foul in spite of catheterism and washing out. In addition to this the specific gravity of the urine began to drop so as to vary from 1004 to 1007. As this condition so often precedes renal disease and uræmia in these cases of prostatic obstruction I divided the vasa early in 1897. From that time forward the urine, amongst other changes, gradually returned to a normal density and the general condition of the patient improved, though he continued to be, and still is, largely dependent on the catheter. He uses it much more easily and, as I am told by his friends, is in good general health. He doubtless failed to appreciate the renal improvement, which I have similarly observed in other instances as being probably connected with mechanical reasons. The patient doubtless measured the success of the vasectomy, as others do, relatively as to whether he could or could not dispense with his instrument, without sufficient regard to the less striking contingencies of catheter life. This patient should properly occupy a place in the second group, but I thought it better to take him at his word as one whom vasectomy had not benefited. The substitution of a good contractile bladder for one that obstruction had worn out would probably suffice to complete the cure. I will take one more instance which may properly be considered in this group from the patient's point of view, though, as with the preceding case, I decline to agree with the patient. It has its lesson to teach which may be the more conveniently learnt in this place.

A man, aged 74 years, was operated upon for stone by litholapaxy by me in 1894. The condition was complicated with a large prostate for which he had to use a catheter. The operation was not an easy one by reason of the former. He had two recurrences in the course of the two following years which I mainly attributed to the obstructing prostate, so I divided both vasa in 1896, with an interval of some weeks between each. He has had no recurrence of stone, can pass his catheter quite easily, keeps free from cystitis, goes to Scotland to fish (a sport which he previously had to abandon), and is now not entirely dependent on the catheter. For a man at the age of 80 years I should say that he was in excellent health, and yet because he is not able to dispense with the instrument entirely he is not disposed to admit that vasectomy did him much good. I am not inclined to agree with him and consequently I should put him also in the second group.

My experience in litholapaxy as illustrated in a recent series of 100 cases[5] leads me to believe that vasectomy has proved an important aid in preventing the recurrence of stone after operation when complicated with enlarged prostate. It probably effects this by providing a free and more dependent exit from the bladder as well as by diminishing the large amount of tenacious mucus which the enlarging prostate both provokes and helps to supply and which lessens materially as the gland shrinks.

I can hardly recall an instance of vasectomy or torsion of the vas for hypertrophy of the prostate where good has not followed though it may not at once be appreciated by the patient. It is not always relative as to whether or not the patient can or cannot dispense with the catheter. Nor is credit always given in this group of cases to the fact that though chronic prostatic obstruction had already caused permanent structural damage to the bladder as the organ for expelling urine and not merely containing it, the further progress of an obstructive disease was arrested by obliteration of the vasa and life was thus indefinitely preserved and rendered tolerable. Though in the case of the eye a cataract operation is successful this does not necessarily imply that spectacles can be invariably dispensed with.

In one instance benefit was slow in coming where the obstruction had previously been of a very chronic character and the bladder had become much weakened and fasciculated. It was found six months after a portion of one of the vasa had been excised and the ends ligatured in a loop that the divided ends had reunited and the continuity and use of the duct had been re-established. I have the specimen, which I subsequently excised and then torsed the freshly divided ends separately. Benefit followed upon this. The specimen was carefully examined for me by Mr. J. G. Pardoe. I could hardly think, unless I had seen it, that this was possible; at all events I have not met with another instance.

In conclusion, surgery may be said to be entering upon a new phase of research for therapeutical purposes. Thyroidectomy and oöphorectomy have produced results so remarkable and changes in the organism so profound that complete removal, except for the express purpose of saving life, is in the first instance condemned as totally inadmissible, and in the second instance is deprecated by a large and constantly growing number of surgeons.

The effect of castration on youthful males for the purposes of the harem has been known for centuries. The effect upon adult and aged men has only recently been investigated. In children the results are not dangerous to life; in the aged, apart from the shock of such a severe surgical mutilation, they are, in some cases at all events, dangerous to reason if not to life.

The explanation offered by physiology is the well-known theory of "internal secretion." This theory, proved so strikingly correct in the case of the thyroid, may, although the testis is not a ductless gland, be equally applicable to the latter organ. In any case it is incontestible that most serious results follow total removal of both testes, whereas I can confidently assert from my seven years' experience of the operation that double vasectomy, performed in the manner which I have described in a previous paper,[6] causes no untoward results whatever.

ON IMMUNITY AGAINST PROTEIDS.

BY WALTER MYERS, M.A., M.B. CANTAB., B.SC. LOND.,
JOHN LUCAS WALKER STUDENT IN THE UNIVERSITY OF CAMBRIDGE.

PRELIMINARY ACCOUNT.

IT is assumed in each of the two theories of immunity which are dominant at the present time—viz., Ehrlich's "seitenkette" or side-chain theory and Metchnikoff's phagocytic theory—that immunity is merely a special case of assimilation. According to these views, for every substance assimilated by a living organism there is present somewhere in that organism a specific anti-substance, and in fact the chief difference between them is whether the anti-substances are produced by leucocytes or by other cells of the body. From the standpoint of immunity the toxic action of a toxin is a matter of accident, indeed of indifference, since a toxin does not produce its antitoxin by virtue of its toxic power, but because on introduction into the animal body in such a way that its immediate destruction is avoided it is assimilated. With the object of obtaining evidence as to the validity of this assumption the following experiments were undertaken with a view to ascertaining what changes, if any, are to be observed in the blood serum when proteids of various classes are introduced into the animal body in steadily increasing amounts. In order to avoid destruction by the digestive ferments of the alimentary tract these substances were not given by the mouth, but were injected intra-peritoneally. As experimental animals rabbits were used and the proteids employed were the following: (1) crystallised egg albumen from the white of fowl's egg; (2) serum globulin from the sheep; (3) serum globulin from the bullock; and (4) Witte's "peptone."

1. *Crystallised egg albumen.*—This was prepared from the white of fowl's eggs by the method recommended by Hopkins and Pinkus.[1] According to Hopkins this purified proteid is to be regarded as a single chemical substance. After repeated intra-peritoneal injections of this albumen continued for two months, the serum of rabbits acquired the power of forming a dense precipitate when added to solutions of crystallised egg albumen. The formation of this precipitate occurred at the ordinary temperature of the laboratory, but was accelerated at 37° C.[2] In very many control experiments neither the serum of normal rabbits nor any of the immunised rabbits mentioned below ever had this action. This precipitate is soluble in 2 per cent. sodium chloride solution and the solution gives the ordinary proteid reactions. The serum of a rabbit treated with egg albumen from the fowl forms a slight precipitate with the albumen from the white of duck's eggs, but not nearly so much as is thrown down from solutions of the same strength of fowl's albumen. I was unable to obtain duck's egg-albumen in a crystalline form, and the precipitation which occurred with it is doubtless due to the presence in small quantity in it of the albumen present in fowl's egg or of a closely allied albumen. The serum thus obtained has no precipitating action on the globulin prepared from sheep's serum, nor on that from bullock's serum, nor on serum albumen from the sheep or bullock. It was likewise without precipitating action on Witte's "peptone." By these injections, therefore, a specific anti-body had been produced—an *anti-proteid* or *precipitin* which had the power of throwing down the egg albumen into a solid insoluble state. The chemical nature of this reaction remains to be investigated and we may conveniently call the precipitate formed by the action of the precipitin the *precipitum*.

2. *Serum globulin from the sheep.*—Sheep's serum was half saturated with ammonium sulphate at laboratory temperature; the precipitate after filtering was washed with saturated ammonium sulphate, dissolved by the addition of water, and again precipitated by semi-saturation with ammonium sulphate. After several precipitations the globulin was dried on glass plates at 37° C. In this case also continued intra-peritoneal injection led to the appearance in the serum of a precipitin. This antiglobulin serum had no action on egg albumen or upon Witte's "peptone," although with the similarly prepared globulins from bullock's serum a small precipitum was obtained after 15 hours at 37° C.

The precipitum from sheep's globulin is soluble in 2 per cent. saline solution and gives the ordinary proteid reactions. The serum of the rabbit immunised against sheep's globulin had also acquired another property—namely, that of agglutinating the red corpuscles of the sheep. In order to be sure of removing all traces of serum the defibrinated blood was diluted ten times with saline solution (0·8 per cent.). After centrifugalisation the clear fluid was removed and the process repeated several times. Finally, a suspension was made of one part of blood in 40 of saline solution.[3] The agglutination was unmistakeable after the mixtures had been for an hour in the incubator at 37° C. The agglutinating action was only present in the anti-sheep's globulin serum, it was absent in the sera obtained by immunisation against bullock's globulin, egg albumen (fowl's), Witte's "peptone," and also in sera from normal rabbits. This action is doubtless due to the presence of the same, or of a closely allied, substance in the sheep's red corpuscles and in the "globulin" from sheep's serum as above prepared.

This anti-globulin serum also clumps the washed red corpuscles of the fowl. I have not found this agglutinating power in any other sera obtained from normal or other rabbits. It follows from these facts that the product here called "sheep's globulin" is a mixture of substances. The main portion of the precipitum given by its precipitin is formed from a substance which is not present in the "serum globulin" of the bullock. One substance present in small quantity in the sheep's globulin is, however, also present in bullock's globulin, since the precipitin of sheep's globulin gives a small precipitum with bullock's globulin. This substance common to the two globulins is not present in red corpuscles of the sheep or fowl, since the precipitin for bullock's globulin does not agglutinate these corpuscles. Further, we must suppose that there are two other substances in the serum globulin of the sheep, one present in fowl's red corpuscles and the other present in those of the sheep, since, as the following experiment shows, immunisation against sheep's globulin leads to the appearance in the serum of two distinct agglutinins, for sheep's and for fowl's corpuscles respectively. If the serum of a rabbit immunised against sheep's globulin be allowed to agglutinate washed corpuscles of the sheep the clear fluid left above the corpuscles will not now agglutinate fresh corpuscles of the sheep if sufficient corpuscles have been used on the first instance. But this fluid still has the power of agglutinating fowl's corpuscles. And conversely after anti-globulin has agglutinated fowl's corpuscles, it has lost the power of agglutinating fresh fowl's corpuscles, but will still agglutinate those of the sheep.

3. *Serum globulin from the bullock.*—This product was prepared in the same way as the serum globulin from the sheep. And here, too, a specific precipitin made its appearance in the serum of the immunised animal. And just as the precipitin for sheep's globulin gives rise to a slight precipitum with bullock's globulin, so the precipitin for bullock's globulin causes a slight precipitum with sheep's globulin; in each case the precipitum is very much smaller than that given with the globulin by which the precipitin was produced. As has been mentioned, the precipitin for bullock's globulin did not agglutinate sheep's corpuscles or bullock's corpuscles.

4. *Witte's "peptone."*—Commercial Witte's "peptone" was dissolved in physiological saline solution, boiled, cooled, and filtered. Immunisation led to the appearance of substances in the serum which produced a precipitum in Witte's "peptone" at 37° C. Control experiments gave absolutely negative results. Most remarkable was the fact that the precipitum after careful washing with 0·8 per cent. saline solution and after solution in 2 per cent. saline did not give the biuret reaction, though it gave the other general reactions of proteids. The fluid removed after centrifugalisation gave a distinct biuret reaction. Here, then, the precipitum belonged to an entirely different class of proteids from the original body.

The effect of heat on the precipitins of egg albumen, of

[1] After several washings and re-precipitations the precipitate was dried on plates. A mixture of ammonium sulphate and proteid crystals was thus obtained. Journal of Physiology, vol. xxiii.

[2] It is necessary to remove any excess of ammonium sulphate by dialysis or the precipitation will not take place.

[3] The serum of rabbits lakes the corpuscles of the sheep. This hæmolytic action may be abolished by heating the serum to 50° C. for half an hour. In all the agglutinating experiments mentioned in this paper the sera were thus heated.

the serum globulins of the bullock and sheep was similar in so far that heating to 56° C. for half an hour led to no appreciable weakening of their action. On the precipitins for Witte's "peptone" heating to 56° C. for half an hour had a marked weakening action, although the precipitins were not entirely destroyed. Adding normal rabbit's serum markedly increases the precipitating action of this heated serum, although normal serum itself remained quite clear with the "peptone." In this respect the "peptone" precipitin is similar to the hæmolysins and the bacteriolysins, but the number of substances involved in this reaction is so large that much further investigation is necessary before definitely contrasting this with the other precipitins.

A number of experiments were made to ascertain whether the precipitin is used up in the formation of the precipitum. A mixture of the precipitins of bullock's globulin and egg albumen was added to a solution of egg albumen. After standing at 37° C. for 15 hours the mixture was centrifugalised and the clear fluid was tested for the presence of the precipitins. It was found to give a precipitum with bullock's globulin but to give none with egg albumen. At the same time a control experiment was made with a mixture of the precipitins of egg albumen and bullock's globulin with bullock's globulin. In this case the clear fluid precipitated with egg albumen but not with bullock's globulin. Experiments of a similar kind with the precipitins of egg albumen and sheep's globulin were made, and in this case also one or other of the precipitins disappeared. From these experiments it is concluded that the precipitins are used up in the course of their action, and bearing in mind their specificity this is strong evidence that the action of these bodies is chemical.

In this preliminary account of the precipitins no attempt has been made to arrange the proteids on which they act in a systematic manner. But it is clear that the precipitins gave us a means of distinguishing between various proteids and mixtures of proteids. And at present, at least, this animal test is more delicate than any chemical method of discrimination available.

These experiments give, I think, strong support to the view that the production of immunity is due to processes of assimilation, and they also explain a physiological point which has long been a subject of discussion. When injected into the circulation peptone disappears very quickly from the blood-stream. Practically nothing is known as to the fate of the peptone which thus vanishes. But clearly this disappearance of peptone is exactly paralleled by the disappearance of the tetanus toxin from the blood-stream. In both cases we produce by immunisation a specific anti-substance. And just as in Wassermann's experiment tetanus toxin is neutralised by an emulsion of fresh spinal cord, so experiments are on record in which peptone has been neutralised *in vitro* by pieces of small intestine.[4] The instability of the anti-body for Witte's peptone and its reactivation by normal serum, showing in other words that it can form *precipitoids* analogous to the toxoids, has already been mentioned.

Finally, these experiments give the explanation of certain facts about which a good deal has been written though but little has been determined by experiment. Kraus's precipitates, for instance, and the precipitates formed by adding anti-eel's serum to eel's serum, or white of egg, are examples of the precipitins.[5]

The connexion of these experiments with the mechanism of agglutination remains to be mentioned. Without discussing the question in detail it may be said that three explanations of agglutination have so far been put forward. In the first place Grüber explains it by assuming that the surface of the micro-organisms becomes sticky. In favour of this view are certain microscopical appearances in the case of motile micro-organisms and the swelling up of the membranes of the micro-organisms. Against it, however, is the circumstance that non-motile bacteria and red corpuscles can also be agglutinated, and though stickiness would account for the cells remaining together when once in contact it gives no account of the way in which they are brought together. This view is untenable because agglutination is sometimes very rapid; it may occur, for instance, in a few minutes—that is, too quickly to be explained by diffusion currents or Brownian movements; secondly, because in agglutination work is done for which the viscous theory provides no source of energy; and thirdly, because the cells not only agglutinate but they settle much more rapidly than the control suspensions.

A second explanation is that the cells are brought together by the contraction of a clot. This view must be described as fanciful since even its adherents admit that the clot is invisible both to the naked eye and to high microscopical powers.

The third view is that of Bordet who regards the phenomenon as analogous to the clearing of inorganic suspensions. Bordet ascribes it to "diminished molecular adhesion" between the cells and the fluid bathing them.

It has already been mentioned that the precipitin of sheep's globulin agglutinates washed red corpuscles of the sheep. Now, if sheep's corpuscles be laked by the addition of distilled water this precipitin causes a precipitate to form in these laked corpuscles. Bullock's globulin precipitin, on the other hand, does not agglutinate these corpuscles and it does not give rise to this precipitate with the laked corpuscles. Similarly, other non-agglutinating sera—e.g., anti-egg-albumen, anti-Witte-"peptone," and normal rabbit's sera—give negative results with laked corpuscles of the sheep. Normal horse serum agglutinates rabbit's corpuscles and also gives a precipitate with the laked corpuscles. On the other hand, a solution of a horse serum that had been kept dried for several years did not agglutinate rabbit's corpuscles and did not produce any precipitate in the laked corpuscles.

We see, then, that these sera which *agglutinate the corpuscles also produce a precipitate in the laked corpuscles*, whether these sera contain artificially produced or naturally occurring agglutinins. If this precipitation occurs in laked corpuscles it should also occur in the uninjured corpuscles. And arguing from the production of precipitins against proteids as above described we should, indeed, expect that on immunising against red corpuscles we should obtain a serum which produces a precipitum in the red corpuscle itself—that is, which makes the substance of the red corpuscle less soluble in plasma or serum or salt solution.[6] We are now in a position to explain the agglutination of the red corpuscles. Bordet[7] has shown that this process depends on some change in the corpuscles and also on the nature of the fluid by which they are surrounded. We may have corpuscles that have undergone the change requisite for agglutination but which do not agglutinate, just as for the agglutination of silica and other organic precipitates the fluid bathing them must have certain definite properties. We see the two factors in this process of agglutination in some experiments of Danyse,[8] which, after repetition, I can fully confirm, though I differ from him entirely in his deductions from them. Ammonia in sufficient concentration lakes the red corpuscles of the goose. If a concentration sufficiently low be taken no hæmolysis occurs. Taking a suspension of these corpuscles in physiological saline solution, containing ammonia in amount just insufficient to produce hæmolysis, on adding to the suspension any of the phosphates of sodium, agglutination very rapidly occurs. Ammonia or the sodium phosphate alone do not produce agglutination. The ammonia clearly produces some change in the corpuscles which renders them agglutinable in a suitable medium. Now ammonia forms, as has been known for many years, a product called "histon" from the red corpuscle of the goose (this is not mentioned by Danyse). Histon is soluble in a certain amount of ammonia, forming a viscid solution; with an insufficient quantity it remains undissolved (Kossel).[9] The following table is quoted as an example illustrating these statements. In each tube 20 cubic centimetres of a 1 per cent. suspension of defibrinated goose's blood in saline solution (0·8 per cent.) was placed, and to each tube 2 cubic centimetres of sodium phosphate (Na_2HPO_4, 1 per cent. in 0·8 per cent. saline) was added. Decreasing

[6] Evidence of the similarity at least of the agglutinins and the precipitins is given by the fact that they are uninjured by exposure to 56° C. for half an hour; and secondly, that both kinds of substances disappear in the course of their action. That the anti-bodies to Witte's "peptone" are destroyed at 56° C. does not affect the similarity, for, as above mentioned, the changes resulting in "Witte's peptone" are further reaching than in the case of coagulable proteids.

Ammonia, then, acts as a precipitin on the red corpuscles in a certain strength, forming insoluble histon within the corpuscle. When the medium is rendered suitable by the addition of sodium phosphate the corpuscles agglutinate. Agglutination consists, therefore, of two processes. In the first place a chemical change in the corpuscle by which some proteid becomes insoluble or relatively less soluble in the serum. This corresponds to the action of the precipitins on their corresponding proteids, and, indeed, is an instance of the action of a precipitin under special circumstances. The corpuscle is now ready for the second stage, in which it is carried down as mica can be carried down by alcohol or other inorganic precipitates by the addition of various salts, especially those of acids or bases of a high valency. The latter phenomena are generally regarded as effects of surface tension, and in this connexion one or two known, but so far unconnected, facts in reference to agglutination may be mentioned which are all in favour of surface tension playing a part in the second stage of this process. The striking feature of agglutination is the smaller surface relatively to their mass which the clumped cells possess in comparison with the unclumped cells. This is exactly what would be produced when particles float in a fluid which does not wet them. The surface of the fluid in contact with the particles here tends to be as small as possible. This result is attained by the particles agglutinating. It need hardly be pointed out that the energy of surface tension is ample to account for the work done in agglutination. Now the change brought about by a precipitin is that tending to make the surface of the fluid in contact with the solid as small as possible. If a solid immersed in a fluid be soluble in the fluid the surface between the two tends to increase to a maximum, or, in other words, the solid dissolves. If the solid become less and less soluble the sign of the surface tension changes—that is, the surface between the two tends to become as small as possible.[10] It may further be mentioned that in all cases of agglutination rise of temperature hastens the process.[11]

In conclusion, the precipitin or chemical stage and the surface tension or physical stage are efficient causes of agglutination, though it is possible that in the case of motile micro-organisms an increase in the viscosity of their surfaces also plays a part in the process.

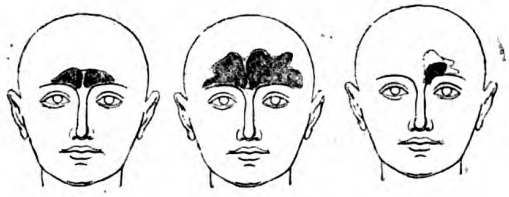
Cambridge.

[10] Hence the assumption of a fatty membrane for the red corpuscles explains rouleaux formation. Shattock (Journal of Pathology and Bacteriology, 1900, No. 111) regards agglutination as an exaggerated rouleaux formation, though he does not discuss the explanation of these processes.

[11] It may be objected that the temperature only influences the first or chemical stage and not the second, surface tension action. In the case of ricin, however, I have found that the second stage is also hastened by rise of temperature. If ricin act on guinea-pig's corpuscles at 37° C. and after 12 hours the fluid be removed the corpuscles can be shaken apart and washed with saline. The corpuscles suspended in saline will agglutinate, although the ricin has been removed, and this agglutination is quicker at 37° C. than at room temperature. Hence rise of temperature influences the second stage of agglutination in this case.

CHRONIC EMPYEMA OF THE FRONTAL SINUS WITH NOTES ON THE TREATMENT OF FOURTEEN CASES.

BY HERBERT TILLEY, M.D. LOND., F.R.C.S. ENG.,



SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE, AND LECTURER ON DISEASES OF THE NOSE AND THROAT, LONDON POST-GRADUATE COLLEGE.

IN that general advance in treatment which has been made in the more special branches of medicine and surgery during the past decade, it may be said without fear of contradiction that a prominent place must be accorded to the improved methods of dealing with diseases of the nose and more especially those met with in connexion with the nasal accessory cavities—e.g., the maxillary antrum, and the ethmoidal, sphenoidal, and frontal sinuses.

The present article deals only with the most frequent chronic affection of the frontal sinus—viz., chronic suppuration or empyema.

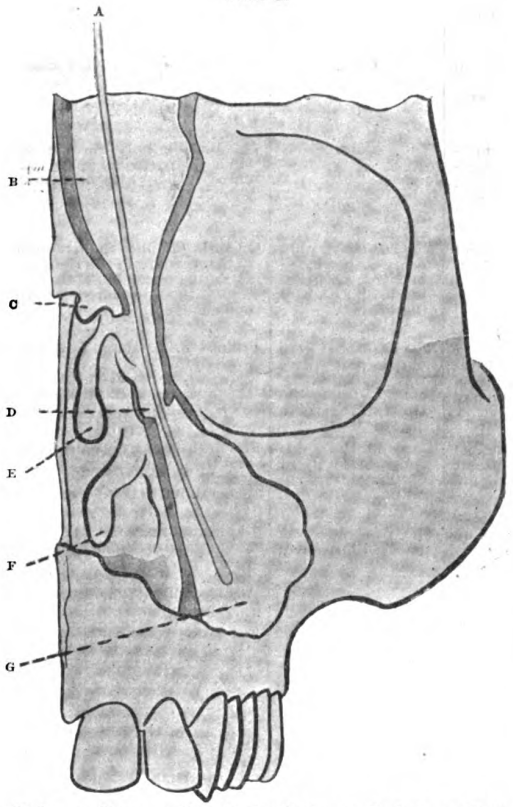
To those whose thoughts are not often centred upon the regions under discussion and whose recollections of the anatomy of the nose and its accessory cavities are possibly somewhat vague, it may be well to state a few facts relative to the disposition of these parts and to lay more particular stress upon such of them as are of importance to the surgeon. "The frontal sinuses are contained in the lower part of the frontal bone above the root of the nose and inner ends of the eyebrows" (Quain). They begin to develop about the seventh year but remain small until puberty when they undergo rapid development. 1. They vary much in size even in the same individual and may be absent on one or both sides (Fig. 1, A, represents sinuses of average size). 2. A complete

FIG. 1.

A B C

In diagram A the sinuses are of normal size; in B they are unusually large. C indicates the amount of anterior wall (dark shading) which it is necessary to remove to thoroughly curette a sinus of normal size (indicated by dotted line).

and imperforate bony septum nearly always separates the sinuses in health, but in disease it is not uncommon for the cavities to communicate with one another through a pathological opening in the septum (Fig. 1, B). 3. In exceptional cases the frontal bone may be almost hollowed out by the sinuses so that they extend outwards to the temporal fossæ, upwards to the frontal eminence, and posteriorly almost to the junction of the frontal bone with the small wings of the sphenoid (Fig. 1, B). 4. The external configuration of the forehead or eyebrow gives no clue whatever to the size of the sinuses underneath. 5. The fronto-nasal canal passes through the anterior ethmoidal cells and opens into the middle meatus of the nose at the anterior and upper part of the hiatus semilunaris into which curvilinear depression are also found the ostia or openings of the maxillary antrum and the anterior ethmoidal cells. 6. In many cases the frontal sinus is in almost direct communication with the antrum, as seen in Fig. 2.[1] It will be noted that the fronto-nasal passage terminates very near the antral ostium, from which a fold of mucous membrane extends upwards and inwards, forming a sort of pocket at the bottom of which is the antral opening. Consequently a discharge of pus from the higher sinus would tend to fill the antrum before it appeared in the nasal cavity, so that the antrum may act not only as a generator but also as a recepticle of purulent discharge. 7. The direction and patency of the fronto-nasal canal varies greatly. From above downwards its direction is slightly backwards, and it



[1] I am indebted to Dr. Filliebrown, Boston, Mass., for permission to use the diagram.

may be so curved or tortuous that it would be impossible to enter the sinus from below without making a false passage. In long-standing cases of chronic suppuration of the sinus or ethmoidal cells it is often quite easy to pass a suitably curved cannula into the frontal sinus from the nose.

The examination of 120 skulls, kindly placed at my disposal by my former teacher, Professor G. D. Thane, showed that if a small quarter-inch trephine is applied to the lower part of the frontal bone included between the middle line and a line drawn vertically upwards from the internal angular process it will in all cases open the sinus on that side if one exists.[2]

Etiology of chronic suppuration.—The history of these cases would seem to indicate that the condition may arise as a sequence of an attack of acute suppuration which does not completely recover, possibly because of inefficient drainage from the sinus. Such acute attacks are not uncommonly of influenzal origin or follow in the wake of an acute rhinitis. In many cases the highest sinus is affected by septic infection from one of the other accessory cavities, such as the antrum or ethmoidal cells. I believe this source of infection is the commonest one, and Fig. 2 shows how easy it is for the upper sinus to be affected from the lower one. Similarly, chronic suppuration occurring in the thin-walled

FIG. 2.

ethmoidal cells through which the fronto-nasal canal runs would almost certainly infect the frontal sinus, especially if, as is generally the case, coincident inflammatory changes in the middle meatus hamper the free discharge of pus into the nasal cavity.

Symptoms.—The symptoms of chronic frontal sinus empyema are three in number—(1) a purulent, non-fœtid nasal discharge; (2) frontal or supra-orbital headache or feelings of discomfort such as a heavy weight or tension in the forehead; and (3) more or less well-marked nasal obstruction caused by the growth of polypi or other chronic inflammatory products within the nasal cavity.

The first symptom is a constant one. The pus is seen in the middle meatus and it is rarely fœtid. The discharge may be profuse, necessitating the use of from 10 to 12 handkerchiefs a day. The flow is not so much influenced by the patient's position as is the case in antral suppuration.

Headache may be taken to indicate that pus is retained in the sinus under tension. I have never met with this symptom when the drainage into the nose has been free, but have often cured it by removal of polypi or other obstruction from the middle meatal region. External pressure upwards and inwards on the floor of the sinus may be productive of pain when compared with similar pressure on the normal side, but here again much depends upon whether or not the pus is retained under tension.

In cases of long standing the middle meatus is always more or less blocked with chronic inflammatory products such as polypi, granulations, or sodden congested mucous membrane. If these are removed the anterior ethmoidal region is represented by a mass of granulation tissue bathed in pus, amongst which a blunt probe easily detects tiny spicules of bone or abuts against those remnants of the bony skeleton of the ethmoid which have only partially succumbed to the ravages of a rarefying osteitis. From this lateral mass hangs loosely the middle turbinal in which chronic inflammatory changes identical with those just described have also taken place.

In addition to the symptoms already described the patient's troubles may be aggravated by a dry throat, catarrhal deafness, and a sense of depression, apathy, and inability to work mainly caused by the nasal obstruction already referred to and partly to the chronic absorption of septic matter from the nasal mucous membranes.

Chronic frontal sinus empyema is not uncommonly bilateral; in five out of 12 cases here recorded this was the case. Under such circumstances the sinuses may discharge into their corresponding nasal cavity, being separated from one another by an imperforate septum (see Cases 6 and 13), or through a perforation in the septum the cavities may communicate and only empty into one side of the nose (see Case 13).

Diagnosis.—A purulent discharge in the middle meatal region almost invariably indicates suppuration of one or more of the nasal accessory sinuses—antral, ethmoidal, or frontal. Headache and nasal obstruction are also symptoms common to empyema of each of these cavities. Hence in arriving at a differential diagnosis each sinus must be carefully examined in detail and the surgeon will find that not rarely they are simultaneously diseased. Since the maxillary sinus is more frequently diseased than the ethmoidal or frontal, it is a good rule to regard every case presenting the characteristic symptoms as one of antral suppuration until examination proves this presumption to be wrong.

Transillumination of the antrum by means of a small electric lamp held in the mouth will as a general rule afford strong presumptive evidence of the presence or absence of pus in the cavity. If any doubt exists the sinus should be explored by a fine trocar and cannula (Lichtwitz's) passed into it from the nose. This little operation implies a preliminary cocainisation of the anterior half of the inferior meatus and then passing the trocar and cannula between the anterior end of the inferior turbinal and the outer wall of the nose in a direction outwards and backwards until the inner antral wall is pierced. The trocar is removed leaving the cannula in position, and on irrigation with warm saline or boric lotion absolute positive or negative evidence of suppuration is at once obtained. With cocaine, care, and a little dexterity the latter operation can be performed with ease and almost painlessly, while it is the only positive test which we possess in the diagnosis of antral suppuration. If such procedures give negative evidence the source of the purulent discharge must be sought for in the ethmoidal or frontal sinuses. In chronic cases the latter cavities are almost always associated in disease. The clinical signs of ethmoidal suppuration have already been referred to—viz., a purulent discharge in the middle meatus associated with a swollen polypoid or granular degeneration of the mucous membrane of the anterior ethmoidal region, amongst which a blunt probe easily detects areas of exposed bone or even loose spicules of the same in various stages of rarefying osteitis. To examine the frontal sinus the middle meatus should be cleansed with wool mops and an attempt made to pass a suitably curved cannula into the higher sinus, and if successful its cavity may then be irrigated and the nature of the contents ascertained. The presence of the cannula in the sinus may be further assured by placing one end of an aural auscultation-tube on the floor of the sinus and the other in the surgeon's ear; on injecting the lotion

14 CASES OF CHRONIC EMPYEMA OF THE FRONTAL SINUS.

No.	Sex and age.	Date when seen.	Duration of symptoms.	Sinuses involved.	Treatment.	Result.	Remarks.
1	M., 38 years.	October, 1896.	18 years.*	Double frontal sinuses; double maxillary sinus (empyema).	Alveolar drainage of antra; external radical operation on the frontal sinuses.	Sinuses cured. There was a slight discharge in irrigation of the antra (February, 1900).	The patient nearly died under operation owing to the post-nasal space not having been plugged prior to operation; blood, therefore, flowed freely into the lungs during operation.
2	F., 22 years.	June, 1897.	7 years.	Both frontal sinuses and ethmoids.	External radical operation.	Fatal, after seven months suffering, from chronic septic osteomyelitis.†	This, my only fatal case, was certainly due to imperfect drainage into the nose and tightly stitching up the wound at the close of operation. Suppuration recurred in the sinuses and pus entered the freshly opened diploë of the frontal bone. Seven similar cases have been recorded.
3	F., 37 years.	March, 1898.	5 years.	The left frontal sinus and both maxillary antra.	Radical operation on the left sinus and antrum; intra-nasal opening and irrigation of the right antrum.	Cure.	The drainage in this case was secured by Luc's ‡ method (*vide* infra).
4	F., 19 years.	April, 1899.	5 years.	Both frontal sinuses.	Radical operation on both sinuses at intervals of three months.	Cure.	The drainage in this case was secured by Luc's method.
5	F., 36 years.	May, 1899.	25 years.	The right frontal sinus and the right maxillary antrum.	Removal of mid-turbinal and irrigation of the sinus; alveolar drainage of the antrum.	Cure.	This is the only chronic frontal sinus empyema I have known cured without external operation.
6	M., 35 years.	June, 1899.	10 years.	Both frontal sinuses.	Irrigation of sinuses and intra-nasal treatment.	The headaches were completely cured and the discharge was greatly diminished.	On syringing into the left sinus the fluid returns from the right nostril, showing perforation of the septum. The patient only requires to use one handkerchief a day.
7	M., 52 years.	July, 1899.	9 years.	The right frontal sinus and the right maxillary antrum.	Intra-nasal treatment and sinus irrigation; alveolar drainage of the right antrum.	The headaches were cured but there was a slight discharge from the sinus and antrum.	Profuse hæmorrhage (arterial) followed puncture of the alveolus. It was only checked by plugging the antrum and middle meatus with gauze.
8	F., 27 years.	October, 1899.	3 years.	The left frontal sinus and the left antrum.	External radical operation; alveolar drainage.	Cure of the sinus suppuration; slight discharge from antrum.	The headaches have entirely ceased and the patient has gained 16 lb. in weight since the operation, the general health being excellent.
9	F., 42 years.	October, 1899.	5 years.	The right frontal sinus and antrum.	Radical operation on the sinus; alveolar drainage of the antrum.	The discharge was greatly diminished.	The wound was completely stitched at the close of the operation and the gauze was removed from the nose, followed by irrigation from the nose: an unsatisfactory method.
10	F., 16 years.	December, 1899.	3 years.	The right frontal sinus and antrum.	Radical external operation on the sinus and antrum.	Cure.	The sinus being small, the cavity was practically obliterated by free removal of the anterior bony wall.
11	M., 20 years.	December, 1899.	4 years.	Both frontal sinuses and both maxillary antra.	Radical external operation on the left sinus. Both antra were drained through the alveolus.	Cure.	The sinus being small, was obliterated as in the last case. The resulting depression is scarcely noticeable.
12	F., 30 years.	February, 1900.	3 years.	Both frontal sinuses.	External radical operation.	Relieved, but slight discharge from the sinus continues.	—
13	F., 19 years.	April, 1900.	2 years.	Both frontal sinuses.	External radical operation.	Cure.	The sinuses communicated through the septum. They were very large (Fig. 1B). Although the right sinus was diseased there was never any trace of pus or disease in the right nasal cavity.
14	F., 50 years.	May, 1900.	5 years.	Left frontal sinus and the left maxillary antrum.	External radical operation on the sinus; alveolar drainage of the antrum.	Cure. There was great diminution of the discharge.	The sinus was packed for three days and then syringed out twice daily for a fortnight through a small indiarubber tube passing through the sinus and out of the corresponding nostril.

* *Vide* Brit. Med. Jour., 1897. † *Vide* Brit. Med. Jour., 1899.

‡ Luc's modification of the radical operation involves two special features—(1) draining the sinus by means of a convolvulus tube, the expanded end of which rested in the infundibulum, the lower end projecting from the corresponding nostril; and (2) complete suture of the external wound. The operation is now rarely performed.

mixed with a little air the "bubbling" of the fluid can be distinctly heard within the sinus by the surgeon. Transillumination of the frontal sinus has been shown by Logan Turner to be of little practical value in diagnosis. In old-standing cases the passage of a cannula into the sinus may often be easily carried out, but when it is difficult or impossible it is well to remember that no force should be used in these localities.

In some cases it will perhaps be necessary to remove the diseased ethmoidal cells and anterior portion of the middle turbinal before the continuance of suppuration demonstrates that the source of discharge is in the higher sinus.

When the antrum and the frontal sinus both contain pus it is a nice point to determine whether the first-named cavity acts as a receptacle or generator of pus. In the latter instance, if transillumination gives a very dark shadow under the eye of the affected side we may suspect a thickened and diseased mucous membrane of the antral cavity, indicative of disease originating in that cavity, whereas a lighter shadow would suggest that the sinus was rather a reservoir than a generator of the purulent discharge. Of other diseases, supra-orbital neuralgia with slight swelling of the eyelid is most commonly confounded with frontal sinus empyema, but the absence of nasal symptoms would militate against the latter disease.

Treatment.—Whatever treatment is finally adopted in these cases it is of paramount importance to ensure free drainage from the sinus by removal of all chronic inflammatory growths from the lower end of the fronto-nasal canal. For this purpose the anterior half or more of the middle turbinal, all polypi, granulations, and diseased ethmoidal cells should be removed by means of curette, snare, or forceps. I have no hesitation in saying that many of the failures in the radical operation have been due to the fact that the external operation has been undertaken before free drainage and immunity from re-infection of the sinus have been secured by this important preliminary intra-nasal treatment.

When, however, this has been satisfactorily carried out the further treatment resolves itself into one of two measures: (1) intra-nasal irrigation of the sinus and (2) external radical operation.

1. *Intra-nasal irrigation.*—Little can be said in favour of this as a means of cure. In the first place it rarely succeeds, and what improvement has been noted in some case is probably due to the improved drainage provided by preliminary intra-nasal treatment. Bearing in mind that this irregular sinus is lined by a mucous membrane which has undergone polypoid degeneration and is freely secreting pus we can scarcely expect that irrigation twice or three times a week with a mild antiseptic lotion through a fine cannula will restore it to a normal condition. Furthermore, it is a treatment which can only be carried out by the surgeon himself except in very exceptional cases. I have given the method a fair and prolonged trial in four cases but without any permanent result except in one case (Case 5). The solutions used were boric lotion, hydrogen peroxide, iodoform emulsion, carbolic lotion (1 in 60), and antiseptic alkaline lotions.

A warning.—More than one surgeon has advocated boring into the sinus from the nose. It cannot be too emphatically stated that this method is unjustifiable, bristles with dangers, and has already been responsible for more than one death from meningitis following shortly after the performance of the operation. A glance at the varying anatomy of the region should be sufficient to warn any surgeon of the unwarrantable risks which such a procedure entails. Recently Spiess (Frankfurt) has revived the operation, the manipulation of instruments being carried out under the kindly guidance of the Roentgen rays. To the writer, however, the method seems to add needless difficulties and encumbrances to an unsurgical and unscientific operation which ought not under any circumstances to be contemplated.

2. *External radical operation.*—This involves removal of more or less of the anterior bony wall of the sinus, of its diseased contents, and the provision of free drainage into the nose.

The patient having been anæsthetised, the eyebrow shaved, the skin cleansed, and the posterior choana plugged with a sponge (*vide* Case 1) an incision is made commencing just above the internal palpebral ligament curving upwards and outwards just below the line of the eyebrow to about the junction of the middle and outer thirds of the supra-orbital ridge. The soft parts and periosteum are retracted in the length of the wound and a small disc of bone is removed from the anterior wall of the sinus by means of a chisel and mallet or a quarter-inch trephine. Pus generally exudes at once through the opening as also does the polypoid degenerated mucous membrane. A bent probe is now passed through the opening in the bone to gauge the extent and limits of the sinus. If the cavity is small, and more so if the patient is a male, the surgeon may proceed to remove all the anterior wall so that at the end of the operation the soft parts fall in against the posterior wall and obliterate the sinus. If the sinus is a large one only a portion of the anterior wall should be removed. In this part of the operation care should be taken not to injure the pulley of the superior oblique muscle, which often comes into view. The diseased mucous membrane is next carefully curetted away down to the periosteum and all crevices or extensions of the sinus are searched out with a small curette or sharp spoon. Somewhat free venous hæmorrhage occurs during this part of the operation, but pressure applied by means of small wool sponges soon checks it. The next step is to make a free opening into the nose which can be safely done by means of curved burrs of progressive sizes[3] or with a suitable curette. In this way suppurating anterior ethmoidal cells are destroyed. The communication between the sinus and the nose should at least be capable of admitting an ordinary lead-pencil, because the success of the operation almost entirely depends upon securing free drainage into the nose. It need scarcely be said that great care should be taken in using instruments in these upper ethmoidal regions. The surgeon will find that access to the upper end of the fronto-nasal canal within the sinus is more easily attained if he removes a small portion of the anterior sinus wall situated just above the junction of the frontal and nasal bones (Fig. 1c). This same diagram represents the relative amount of anterior wall which should be removed in order to deal efficiently with a sinus of ordinary dimensions as indicated by the dotted lines. Having thoroughly curetted and dried the sinus it may be swabbed out with zinc chloride 40 grains to one ounce or pure carbolic acid and then packed with a strip of antiseptic gauze. The soft parts are stitched up at once except at the lower angle of the wound through which the end of the gauze projects. In the course of three or four days (if in the meantime the temperature is normal and the wound looks well) about three inches of gauze may be withdrawn and cut off, the process being repeated every third or fourth day until all the gauze is removed and the cavity is lined by healthy granulation tissue when the external wound may be allowed to close.

In three cases I have inserted a small drainage-tube which projects from the inner angle of the external wound (which is stitched up as in the first method) and passes through the nose and out of the external naris. A hole is made in the side of the tube which lies in the sinus so that the latter may be daily irrigated and free drainage provided. The tube can be substituted after the lapse of about ten days for a U-shaped piece of silver wire bent somewhat like a tracheotomy tube so that it keeps open the fronto-nasal canal and can be daily removed for irrigation. Excellent results followed this method, the patients being free from discharge within one month of the operation.

It is unfortunately true that some seven or eight fatal cases of septic osteomyelitis have been recorded after the operation and apparently due to its performance, but it is only fair to say that these have occurred during the evolution of the operation as above described and in all cases they have been due to the fact that free drainage into the nose has not been ensured at the time of the operation, the external wound has been tightly sewn up, and with recurring suppuration the septic matter has been forced into the recently opened diploë of the frontal bone with ultimately fatal results.

In those instances where the antrum also contains pus an alveolar drain should be inserted and the antrum irrigated thoroughly for a few days before the radical operation on the higher sinus is undertaken. If, after the cure of suppuration from the frontal sinus the discharge from the antrum continues in spite of irrigation it may be necessary to explore that cavity in a somewhat similar manner to that described for the upper sinus, and it will often be found to contain a diseased mucous membrane which must be curetted away and the cavity packed or irrigated daily until its lining membrane is healthy.

[3] Made by Meyer and Meltzer, 71, Great Portland-street.

Complications.—Apart from septic inflammation of the frontal bone which ought not to occur, other complications are few and of small importance. It is well, however, to warn the patient beforehand of the possibility of loss of sensation in the skin over the forehead owing to division of the supra-orbital nerve. Temporary diplopia is not uncommon owing to disturbance of or inflammatory exudation around the pulley of the superior oblique muscle. It does not, as a rule, last for more than a week or ten days.

A study of the results attained in the appended list of cases will show that efficient intra-nasal treatment alone will completely relieve headache and nasal obstruction, while in most instances the purulent discharged is diminished. The question therefore arises: "What should determine the surgeon in advising the external radical operation?" The answer will, I think, mainly depend upon the temperament and idiosyncrasies of the patient. Intra-nasal treatment, as in Case 6, may so benefit the patient that he or she may find no inconvenience from a small amount of pus which necessitates the use of only one handkerchief a day, a condition of improvement which the individual referred to speaks of as "cure," although there is a slight discharge of pus from each sinus. Neither can the surgeon regard the improved condition as one calling for immediate radical intervention, much as his surgical instinct may prompt him to regard inimically any pus-producing focus within the body. On the other hand, some patients are particularly sensitive to the presence of any abnormal nasal secretion, and however slight it may be they desire to be entirely rid of the same. Under such circumstances and again where the patient contemplates going abroad or to regions where an occasional skilled examination of the nasal cavities is not obtainable we may advise the external radical operation.

Concerning this procedure it may be said that if due regard is paid to the anatomy of the regions involved and care is taken in carrying out the details already indicated, it is an operation almost free from danger, leaving remarkably little scarring or disfigurement even after extensive removal of bone, and yielding results gratifying alike to both patient and surgeon.

Note.—Since the above article was written I have operated upon three more cases of frontal sinus empyema, the last of which I successfully skin-grafted by Thiersch's method, and the progress of this case leads me to think that this method will give ideal results and greatly minimise the time during which the patient is under treatment.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF PANCREATIC DIABETES DUE TO CALCULI.

BY E. WILLMER PHILLIPS, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a naval pensioner, fifty years of age, and was first seen by me on the evening of Oct. 29th. He was then complaining (1) of passing a little blood per rectum when defecating; (2) a discharge in the interval which stained his shirt; and (3) of great weakness and wasting; he had lost in weight one stone in twelve months. He was a dark, tall, thin man and, except for absence of anæmia, looked as though suffering from malignant disease. There were no abnormal physical signs in his chest and nothing unusual was felt in the abdomen or per rectum. Sometimes he felt restless but lately he had been very drowsy. He had no thirst or polyuria. His tongue was clean and there was no perceptible odour in his breath. His bowels were open twice daily, the motions being very offensive. His pulse was 54 per minute. His urine was of specific gravity 1024; sugar was present, but there was no albumin. On Nov. 1st he passed five pints in 36 hours. On Nov. 3rd analysis showed 8·7 parts of sugar per 1000; no acetone, diacetic, or β-butyric acid was present. I noticed that the stain on his shirt looked greasy (or, as his wife expressed it, "as though vaseline had been smeared over it," and she had great difficulty in washing it out). Upon inquiry she said that the motions were greasy and those I examined were mottled-grey, greasy-looking, and peculiarly offensive; once or twice there was solid fatty material upon cooling.

There were occasional slight pain in the pancreatic region and tenderness upon deep pressure, but nothing could be felt. The optic discs were very white and the man had had temporary amaurosis some time previously. At first he improved slightly upon careful diet, aperients, and pancreatic tabloids, and the extreme drowsiness passed off, but at the end of a month he would eat just what he liked with consequent drowsiness and weakness; one night he became excited and light-headed after a diet of milk, ginger-beer, brandy, sardines, and liver. After these bouts he would starve for a few days and improve, but on the whole the course was one of progressive weakness, aggravated for three weeks by severe hæmorrhage from prolapsed piles. The specific gravity of the urine varied from 1010 to 1032; that passed in the day contained sugar (12·500 per 1000 in May), but that passed at night did not. There was slight peripheral neuritis in the hands and legs. The lung broke down in May and he gradually died from exhaustion on June 14th. There was never any jaundice. I afterwards heard that he had suffered from frequent severe attacks of colic and vomiting for which he was invalided from the navy 20 years ago. Only a partial necropsy was allowed. The liver and kidneys were apparently healthy. The pancreas was hard and its duct was filled with calculi and calcareous matter. The largest mass was situated in the head of the pancreas and was tubular in shape; the next largest was at the splenic end; a third could be felt in the posterior part of the head; the entrance of every branch duct was plugged with concretions. No communication could be found between the pancreatic and common duct or with the duodenum. The substance of the gland was hard but it was not enlarged. It was examined by the Clinical Research Association and the report was as follows: "The pancreas shows great increase of fibrous tissue in parts with atrophy of acini and glandular tubules. A section of moderately large duct shows much shed epithelium from catarrh." The colours of the calculi and débris were chiefly yellowish white and dark grey mixed.

Remarks.—It was evident upon examining the urine and motions that there was obstructive disease of the pancreas, but cases of pancreatic calculi are sufficiently uncommon to merit record. The chief points of interest in this case are first the misleading symptoms for which he sought advice (hæmorrhage and discharge per rectum), and secondly the history of previous severe colic. In a case recorded by Minnich the symptoms of colic, intermittent glycosuria, and fatty motions led to the discovery of pancreatic calculi in the fæces. The peculiar odour of the motions seems to be almost pathognomonic of pancreatic disease; the great prostration and wasting also are more pronounced than in ordinary diabetes.

Southsea.

IMPACTION OF A BEAN WITHIN THE AIR PASSAGES; TRACHEOTOMY; EXPULSION THROUGH THE WOUND; RECOVERY.

BY BRUCE HAMILTON, M.R.C.S. ENG., L.R.C.P. LOND.

THE following case presents features of special interest. A boy, aged 12 years, was playing with dried haricot beans when his elbow was accidentally jerked upwards with the result that a bean which he had been holding in his hand was shot into his mouth; fits of coughing and retching at once commenced.

I saw him within 10 minutes of the occurrence of the accident—viz., at 8.30 P.M. He was complaining of great difficulty in breathing and indicated the supra-sternal notch as the spot where obstruction was most felt. There was no evident laryngeal stridor and the character of the voice may be described best as "ventriloquial." He made many ineffectual attempts to relieve his embarrassment by cramming his fingers down his throat, an act that induced noisy vomiting but failed to give him relief. On examination of the chest no air was found to enter the right lung; the left lung was working naturally. No foreign body was seen in the larynx or trachea. Now and again he coughed up blood-stained mucus. It being

then practically certain that the right bronchus was blocked efforts were made to dislodge the foreign substance. Thumping the back, inversion, violent emesis induced by ipecacuanha wine, alike proved ineffectual, and the boy becoming sleepy he went to bed and slept placidly and uninterruptedly till morning.

Early the following day (12 hours after the accident) a fit of coughing occurred and similar attacks followed at diminishing intervals until at last a continuous struggle for breath terminated with unconsciousness and convulsions. The trachea was opened with one cut of the knife as the patient lay upon the floor where he had fallen, and at once restoration was partially re-established and consciousness returned, but it was not until the incision had been enlarged in a downward direction that a bean, greatly swollen, softened, and ruptured, was expelled through the wound with considerable force. The period of time that elapsed between the first cough in the morning and the onset of convulsions was about 20 minutes. The subsequent history of the case was uneventful.

The right and proper treatment in a case such as that which has been related is immediate tracheotomy, thus obviating the possibility of sudden death from laryngeal spasm should the foreign body become dislodged and be driven upwards; but it is by no means an easy matter to convince the friends of the imperativeness for surgical interference when they see the patient sleeping calmly. In the case in point, though probably there was present some degree of laryngo spasm at the time of operating, as evidenced by the partial restoration of respiration that at once took place after the trachea had been incised, I believe that the spasm was chiefly due to a participation of the adductores vocales in the general convulsive fit consequent upon hypervenosity of the blood rather than to reflex spasm brought about by peripheral irritation of the tracheal nerve-endings. Profuse hæmorrhage followed incision of the skin and may have been a factor in relieving spasm. The reason that asphyxia came on so precipitately towards the last may be partly explained by the nature of the foreign body. The testa would take time to soften and until that had been accomplished no great general increase in size could take place; but once the substance of the cotyledons began to absorb moisture a vast and relatively sudden expansion would occur, and any check upon expansion, such as the walls of the bronchus would have been likely to have exercised, would terminate with the dislocation of the foreign body into the wider lumen of the trachea.

Hampstead, N.W.

A CASE OF ADDISON'S DISEASE; TREATMENT WITH SUPRARENAL EXTRACT; DEATH.

BY EDGAR G. TREVITHICK, M.D. CANTAB.,
PHYSICIAN TO THE CHELTENHAM HOSPITAL.

IN this instance the symptoms of Addison's disease supervened in a man who exhibited in several organs signs of old, but thoroughly and long since arrested, tuberculosis. The bronzing of the skin was observed by the patient's friends two months before his death and became rapidly intensified along with increasing asthenia, chilliness, and gastro-intestinal irritability. Treatment with suprarenal extract was apparently without any avail, but it is only fair to say that this treatment was not instituted until very late in the course of the illness. The following notes give an outline of the case.

The patient was a man, aged 40 years, with a strong family history of tuberculosis. His present illness had begun two months before with darkening of the complexion accompanied or followed by feebleness and nausea. On admission to the Cheltenham General Hospital there was extreme pigmentation of the skin. The scrotum and penis were absolutely black. The face and hands were of a dark brown colour. The skin over the trunk was much pigmented. The legs and the feet were only slightly discoloured. There was some pigmentation on the dorsum of the tongue. The pulse was 66. The temperature was entirely subnormal. The knee-jerks were present. The urine was normal. There was considerable distortion of the spinal column, dating from an attack of spinal caries when 23 years of age. The symptoms most complained of were vomiting, great weakness, and chilliness. Suprarenal extract was administered twice a day without any good effect. Small doses of liquor morphiæ alone appeared of service in checking the vomiting. On the tenth day after admission the temperature, which for several days had never been higher than 97·4° F., suddenly rose to 101°; and with it the pulse-rate, which had averaged 55, increased from 50 to 100. No actual rigor was noticed. But two mornings afterwards the temperature had again fallen to subnormal and the patient was once more complaining much of chilliness. The nurse in charge administered a little stimulant and leaving the bedside was surprised and shocked to find on returning 10 minutes later that death had occurred.

Necropsy.—Signs of old arrested tuberculous disease in the spinal column were found. There were small obsolete strongly encapsuled tuberculous deposits here and there in both lungs and in the bronchial glands. There were no signs of active or even recent tuberculosis in any organ. There was very great displacement of organs due to spinal curvature. The right suprarenal capsule firmly adherent to the under surface of the liver was represented by an olive-shaped mass of dense fibrous tissue. The left capsule was adherent to the tail of the pancreas; it was normal in shape but with its proper substance entirely replaced by fibrous tissue containing several small caseous centres. Owing to spinal curvature the kidneys had fallen away considerably from their normal position and were no longer any guide to the situation of the suprarenals. There was much chronic thickening of the peritoneal and subperitoneal tissue in the neighbourhood of the distorted spinal column and the suprarenals lay in the midst of this sclerosed area. The spleen was diffluent. The liver was very soft and fatty. The heart walls were very thin and soft and rotten.

WESTMINSTER HOSPITAL.

THREE CASES OF PHTHISIS TREATED WITH "TUBERCULIN R."

(Under the care of Dr. W. MURRELL.)

IT is even more important to publish unsuccessful cases than to record those in which improvement has resulted, and especially is this so in connexion with new methods of treatment. Ten years have elapsed since the introduction of Koch's tuberculin, and yet it has not attained to a recognised position in the therapeutics of pulmonary phthisis. It appears to be of very little use in mixed infections or in advanced cases, and the striking beneficial results detailed by Professor Mc Call Anderson in his lecture[1] are certainly exceptional. Professor Anderson gives his patients large doses of cod-liver oil (three ounces a day), and this may account in part for the difference. The reaction produced by Koch's original tuberculin was certainly of some diagnostic value, but with the new tuberculin there is very slight reaction and therefore its use in diagnosis is less.

CASE 1.—An old soldier, aged 41 years, was admitted to Westminster Hospital on August 31st, 1898, suffering from phthisis. He had been ill for three years and during the greater part of that time had been under treatment. His symptoms were cough with muco-purulent expectoration containing tubercle bacilli in abundance, progressive loss of flesh, and night-sweats. His physical signs were deficient movement and dulness over the whole of the right side, with high-pitched breath-sounds accompanied by crepitant râles. Posteriorly there was dulness at the right base up to the angle

[1] THE LANCET of June 16th, page 1703.

of the scapula with feeble breath-sounds and a few soft râles. In the supra-spinous fossa there was cavernous breathing with whispering pectoriloquy. There was no indication of mischief on the left side. The patient had tuberculous disease of the spine in a progressive condition, for which he was wearing a poroplastic jacket. His urine contained a trace of albumin, but no casts were found. His temperature during the first five days was 100° F. at night, but on the following three days was only once above 99°. The "Tuberculin R" treatment was commenced on Sept. 9th. The patient was kept in bed, strict antiseptic precautions were observed, and the temperature was taken every four hours night and day. The following is a list of the injections given:—

No.	Date.	Dose.	Reaction.
1	Sept. 9	$\frac{1}{500}$ mg. in 5 c.c.	99·0° to 100·8° F.
2	,, 12	$\frac{1}{500}$ mg. in 5 c.c.	None.
3	,, 15	$\frac{1}{250}$ mg. in 2 c.c.	98·0° to 100·0° in 7½ hours.
4	,, 16	$\frac{1}{125}$ mg. in 4 c.c.	None.
5	,, 19	$\frac{1}{250}$ mg. in 5 c.c.	None.
6	,, 22	$\frac{1}{10}$ mg. in 2 c.c.	98·0° to 99·8° in 8 hours.
7	,, 27	1 mg. in 1 c.c.	98·6° to 100·2°.
8	,, 30	2 mg. in 2 c.c.	99·0° to 101·2° in 20 hours.
9	Oct. 4	3 mg. in 3 c.c.	99·2° to 101·8° in 12 hours.
10	,, 6	3 mg. in 3 c.c.	99·0° to 101·6° in 24 hours.
11	,, 7	3 mg. in 3 c.c.	99·4° to 101·4° in 16 hours.
12	,, 13	3½ mg. in 3½ c.c.	99·2° to 100·4° in 20 hours.
13	,, 18	4 mg. in 4 c.c.	99·2° to 101·0° in 12 hours.
14	,, 19	4 mg. in 4 c.c.	100·4° to 101·6° in 8 hours.
15	,, 22	4 mg. in 4 c.c.	98·0° to 101·8° in 24 hours.
16	,, 28	3 mg. in 3 c.c.	98·0° to 100·0°.
17	Nov. 10	4 mg. in 4 c.c.	99·0° to 100·8°.
18	,, 18	4 mg. in 4 c.c.	98·0° to 99·6°.
19	,, 27	5 mg. in 5 c.c.	98·0° to 102·4°.
20	Dec. 1	2 mg. in 2 c.c.	None.

From this table it will be seen that in 12 weeks the patient had 20 injections in doses ranging from $\frac{1}{500}$th of a milligramme to five milligrammes. A detailed examination of the condition of the chest was made every week and there was no improvement in the physical signs, but, on the contrary, there was some extension of the mischief at the right apex. The tubercle bacilli were still found in abundance in the expectoration. The general symptoms showed no amelioration and for a considerable period the patient suffered from profuse night-sweats. The only hopeful sign was that the appetite was maintained and that the patient did not lose flesh. He was discharged on Dec. 10th.

CASE 2.—A man, aged 35 years, was admitted to Westminster Hospital on August 5th, 1898. He was in the hospital for pleurisy with effusion on the right side in 1896. He remained well until Christmas, 1897, when he caught a bad cold and since then his cough had never left him. He had night-sweating and there was considerable loss of flesh. On admission the physical signs were impairment of movement at the right apex, dulness on percussion, bronchial breathing in the first and second intercostal spaces, accompanied by moist râles. Moist râles were also heard at the right back up to the angle of the scapula. On the left side there was dulness at the base with moist sounds. Tubercle bacilli were found in abundance in the expectoration. The temperature for four weeks after admission, during which he had only symptomatic treatment, usually reached 103° F. in the evening. On Sept 12th he was given a hypodermic injection of $\frac{1}{500}$th of a milligramme of "tuberculin R" which produced no reaction. On the 14th the dose was repeated without effect and on the 16th it was increased to $\frac{1}{250}$th of a milligramme. On the 22nd at 8 A.M., when the temperature happened to be only 97·0°, he was given $\frac{1}{250}$th of a milligramme and the temperature rose to 99·8°, but whether as the result of the injection it was impossible to determine. On the 27th he was given one milligramme and on the 31st two milligrammes, and again without any positive influence on the temperature. There was no improvement in the physical signs and on Oct. 2nd he took his discharge, his condition being no better than on admission. He died three weeks after leaving the hospital and no post-mortem examination was obtained.

CASE 3.—A man, aged 45 years, was admitted to Westminster Hospital on August 21st, 1897. He stated that he had had a cough since February, 1896, the cough being constant and accompanied by much expectoration. He had a bad attack of hæmoptysis five months before and since then had frequently spat blood, the last time being about a month before admission. He had been steadily losing flesh for over a year, but had not suffered from night-sweats. There was flattening with diminished movement at the right apex in front and the percussion note over the whole of the right side was impaired. At the right apex the breath-sounds were weak and were accompanied by numerous fine râles. In the outer half of the first two intercostal spaces whispering pectoriloquy was obtained. The temperature during the first week usually reached 102° F. in the evening. On August 29th at 11.55 A.M., the temperature being 98°, he was given a hypodermic injection of $\frac{1}{500}$th of a milligramme of tuberculin R. At noon the temperature was 98·8°, and at 1 P.M. 99·6°. It then fell again and at 3 P.M. was 98°. On Sept. 1st at 1.45 P.M. he was given an injection of $\frac{1}{250}$th of a milligramme and at 6 P.M. his temperature was 101·6°. On the 3rd at 9.30 A.M., the temperature being 100°, he was given an injection of $\frac{1}{125}$th of a milligramme and at 10 A.M. the temperature was 101·8°, after which it gradually fell. On the 9th at 6.15 P.M., the temperature being 100°, the patient was given a hypodermic injection of $\frac{1}{83}$rd of a milligramme. At 6.30 the temperature was 101° and at 7 it was 101·8°, after which it gradually fell. The patient was given in all six injections, the maximum being $\frac{1}{50}$th of a milligramme, but there was no improvement either in the symptoms or in the physical signs. His appetite failed to improve, and as he was rapidly losing flesh he was sent home.

Remarks by Dr. MURRELL.—My experience of the treatment of phthisis with tuberculin R has been so limited compared with that of Professor McCall Anderson that it is with some hesitation that I venture to call attention to these cases. My experience would probably have been larger had the results been more favourable. It may be that if cases were carefully selected and only patients in a very early stage treated by this method better results would be secured. Possibly, too, the number of injections was too small, for I believe that in a successful case published by Professor McCall Anderson 47 injections were given in four months. The maximum dose of the new tuberculin is said to be 20 milligrammes, but that is a very large quantity and I have not ventured beyond five milligrammes. The irritation produced at the seat of infection is often a source of trouble and inconvenience to the patient. The expense is a serious consideration and in hospital practice a physician hesitates to recommend his house committee to sanction the employment of a remedy which runs up to 17*s.* a dose. I endeavoured to get it made in England on more reasonable terms, but was told that although the formula was published the exact details were not known. I have no wish to speak unfavourably of tuberculin R and my limited experience would not justify me in doing so, but I am positive that in these particular cases I could have obtained far better results with the formic aldehyde treatment, the details of which I have already published.

MORPETH COTTAGE HOSPITAL.

A CASE OF FRACTURE OF THE LEFT SIDE OF THE SKULL WITH COMPLETE RIGHT HEMIPLEGIA; OPERATION; RECOVERY.

(Under the care of Dr. E. F. L. DE JERSEY.)

IN all cases of depressed fracture of the skull, except in those in young children, it is now the accepted treatment to trephine at once, even in the absence of symptoms and even if the fracture be unaccompanied by a lesion of the scalp. In the following case the coma and the right sided hemiplegia pointed clearly to the lesion on the left motor area, and the fact that pressure over the fracture produced spasm of the right side of the body confirmed the diagnosis. The harmlessness and the value of modern treatment of even extensive fractures of the skull could not be better illustrated than in the case recorded below.

A man, aged 45 years, was admitted into the Morpeth Cottage Hospital on Feb. 22nd, 1900, having been struck on the left side of the head on the 17th with a pole six feet in length and from six to nine inches in diameter. There was complete unconsciousness with right-sided hemiplegia and retention of urine and fæces. The temperature was 102° F. On the day before the patient's admission into the hospital (Feb. 21st) slight crepitation was detected over the left parietal bone at about its centre. There was no external wound or discolouration over the site of the injury, only slight

pitting on pressure. There was slight effusion of blood a little above and in front of the left ear. There were also two black eyes produced by fist-blows. On firm pressure over the site of the fracture spasm of the whole right side of the face and body was produced.

An operation was performed at 3.30 P.M. on Feb. 22nd. An incision was made from a point one inch above the left frontal eminence of the frontal bone and three and three-quarter inches above the left external canthus down to a point half an inch above the lower border of the left parietal bone and two and a half inches above the left external auditory meatus up to a point a little above and behind the left parietal eminence four and a half inches above the left mastoid process and five and a half inches from the starting-point. On raising the flap thus formed an extensive stellate, depressed, fissured, and comminuted fracture was found, the stellate and comminuted portion being situated immediately in front of the left parietal eminence. On raising the depressed and comminuted fragments both the internal and external tables of bone were found to be involved, fragments of bone projecting in all directions into the brain substance, tearing to shreds the dura mater, the arachnoid, and the pia mater lying over the convolutions of the brain. After the removal of the fragments of bone an area of brain two and a half inches by three-quarters of an inch was exposed. From the anterior border of this area in the bone was a fissure extending downwards and forwards into the frontal bone towards the outer border of the left orbit; another fissure extended from the posterior part through the remaining portion of the parietal bone into the occipital bone. This latter fissure was much wider than the anterior one, it being about a quarter of an inch in breadth. Beneath the stellate and comminuted fracture was a large hæmatoma, which was left undisturbed. At a point four inches at right-angles to Reid's line and two inches behind the exterior auditory meatus, being at a point a little posterior to the left parietal eminence, was a cavity extending right into the substance of the brain large enough to admit the little finger quite easily. This cavity corresponded to the upper end of the left Rolandic fissure, thereby involving the upper ends of the left ascending frontal and parietal convolutions, the latter chiefly. This cavity, no doubt, was produced by the injury, but degenerative changes had already set in, as the brain matter round the orifice was quite pulpy and friable. The fracture covered most of the motor area, there being complete right-sided hemiplegia and motor aphasia, showing that the left inferior frontal convolution must have been damaged as well as the parietal convolutions. Some of the difficulty in speech was due to paralysis of the tongue, but after the latter had passed away there was considerable aphasia left. The patient stated when he got the use of his tongue that he could hear everything which was said to him and wished to answer but he could not get his words out. Part of the whole thickness of the parietal bone was replaced, a gauze plug was inserted into the cavity in the brain and brought out under the flap, which was sutured, and a dry dressing was put on. The plug was removed on March 3rd and the wound healed without suppuration.

Before operation the pulse was 40, the breathing was very quiet, almost inaudible, and deep coma was setting in. At 9 P.M. on the evening of the operation the patient was still unconscious but he raised his right leg every now and again. The pulse was quicker and the breathing was stronger. The temperature was 97·5°. He had taken nourishment, and this he had not done before since the injury. He was very restless and kept on raising himself from the pillow. Shoulder bands were put on which kept him still, they being tied to the head of the bed. On Feb. 23rd (the day following the operation) the patient had had a pretty good night though he had been very restless at times. He had said the word "No" and had made signs for a drink. The urine and fæces were passed involuntarily. The temperature was 98·2°.

From the operation the patient steadily improved and never once did the temperature rise above the normal. On Feb. 24th the right arm could be raised slightly. On the 25th the right arm could be moved freely and consciousness was returning. On the 28th the patient tried hard to speak but could not get the words out. He opened his mouth when asked to do so and said small words like "Yes" and "No," but usually he used the latter to questions which were put to him. Consciousness had almost completely returned. On March 7th the patient put out his tongue for the first time. It deviated much to the right. He carried on a little disconnected conversation, there being much motor aphasia. He started taking light solids on this day. On the 12th he gave a statement to the police as to the cause of his injury quite rationally, but with difficulty at times owing to the aphasia. He said that he had a bad memory and could not remember names so well as he could before the injury. On the 16th the patient got up. On April 2nd he walked about the ward quite well and was able to carry on a conversation with very little difficulty. The paralysis had completely disappeared, but there was slight weakness of the right side, specially noticeable by the clench of the two hands. On the 10th the patient was dismissed from the hospital.

Remarks by Dr. DE JERSEY.—The order in which the paralysis disappeared was very prominent. Almost directly after the pressure over the motor area had been relieved movement of the paralysed side returned, starting with the leg, then followed by the upper extremity, the face, and lastly by the tongue. The shoulder movements returned before those of the elbow, and those of the elbow before those of the hand—viz., the finer movements. The upper face being only slightly affected returned to its normal state long before the lower face. The return of the paralysed side to normal brought out very well the fact that the parts which rarely act independently of their fellows on the opposite side are the parts that are usually the least paralysed and consequently are the parts that recover the most quickly.

Before the operation there was retention of urine; after operation there was retention with at times incontinence, the bladder being frequently found above the pubes. The urine was drawn off for five days and the bladder was washed out with a weak solution of boric acid, as there was slight cystitis. Fæces were passed involuntarily for two or three days after the operation; after that there was constipation.

The interesting points in the case are the rapid recovery after the pressure on the brain had been relieved, the signs of relieved pressure appearing before those of shock began to pass off, and consciousness returning comparatively late.

The cavity found at the top of the motor area seemingly has left no bad effects, as also the gaping fissures in the bone extending into the frontal and occipital areas respectively. The fissures were left as approximation of the two sides could not be obtained, although seemingly all wedges of bone likely to cause the gaping were removed. It was thought unwise to make further flaps to discover actually how far these fissures extended, as in all probability no harm would be done by leaving them. This was the case. Another interesting point is the fact that a piece of bone, including both the external and internal table, completely deprived of its periosteum, was replaced and has become firmly adherent to the adjacent bone. Its size was nearly half an inch square.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Porro-Cæsarean Hysterectomy with Retro-peritoneal Treatment of the Stump in a Case of Fibroids Obstructing Labour, with Remarks upon the Relative Advantages of the "Modern Porro" Operation over the Sänger-Cæsarean in most other Cases requiring Abdominal Section.

A MEETING of this society was held on July 5th at 20, Hanover-square, W., Mr. ALBAN DORAN, the President, being in the chair.

Dr. AMAND ROUTH read a paper on Porro-Cæsarean Hysterectomy with Retro-peritoneal Treatment of the Stump in a Case of Fibroids Obstructing Labour, with Remarks upon the Relative Advantages of the "Modern Porro" Operation over the Sänger-Cæsarean in most other Cases requiring Abdominal Section. When the patient was first seen the pelvis was occupied by a large fibroid and the cervix uteri was out of reach above the symphysis. During the thirty-fourth week the pelvic fibroid was rather suddenly drawn up out of the true pelvis and it was hoped that parturition would be naturally performed. As it was found that the head was arrested just above the lower segment of the uterus by two opposing fibroids a Porro-Cæsarean operation was

performed in preference to a panhysterectomy or to Cæsarean section with removal of the appendages. *The operation.*—When the abdomen was opened in the middle line the left broad ligament came into view with the largest fibroid on its right. The incision into the uterus had therefore to be made posteriorly to the left broad ligament and was directly over the placental site. The placenta was stripped off, the membranes were incised, the child was extracted, the placenta and membranes were removed, and the uterus was brought out through the abdominal incision. The operation was then completed by Baer's method. Both mother and child had an uneventful recovery. It was a point worthy of discussion whether supra-vaginal amputation of the uterus (Porro's operation), with retro-peritoneal treatment of the stump, was not safer for the patient in skilled hands than a Sänger-Cæsarean section with sterilisation in all cases of *permanent* obstruction to labour requiring abdominal section, except, perhaps, those due to cancer of the supra-vaginal cervix. When it had been decided that a viable child had to be delivered from a living mother by abdominal section all cases would resolve themselves into three groups: (1) those where hysterectomy (Porro or panhysterectomy) with retention of one or both ovaries was absolutely indicated; (2) those where a Sänger-Cæsarean operation (with or without sterilisation) was absolutely indicated; and (3) those capable of being treated by either operation. It was agreed that a Porro (or panhysterectomy) was absolutely indicated in the following cases: obstructing fibroids, cicatricial stenosis of the vagina where the lochia could not escape, septic endometritis, decomposed fœtus (osteomalacia owing to the fact that removal of the appendages was often curative), uterine hæmorrhage from uterine inertia during Cæsarean section, and after much previous manipulation of the uterus in attempts to extract per vaginam. Sänger-Cæsarean section without sterilisation was, on the other hand, absolutely indicated, instead of a "Porro," where it was considered desirable for the woman to have a chance of another child, and Sänger-Cæsarean section with sterilisation was required (?) in cases of cervical cancer when the supra-vaginal cervix was involved. There only remained, therefore, a third group of cases where a Cæsarean section with sterilisation was usually done, but where it would, in Dr. Routh's opinion, be quite as reasonable to do a modern "Porro." This third group included all cases of sufficient pelvic contraction, and it was in such cases that the relative value of a modern "Porro" operation as compared with a sterilising Sänger-Cæsarean operation demanded serious consideration.

Dr. A. L. GALABIN preferred to call the operation performed by Dr. Routh a Baer-Cæsarean or simply a Cæsarean hysterectomy, as the original operation of Porro was hysterectomy with the uterine stump fixed in the abdominal wound instead of being covered by peritoneum and dropped into the abdomen, as Dr. Routh had done. He thought the best operation had been done and he had performed a Porro's operation in a similar case five years previously. He did not think that pregnancy added to the difficulties of such a hysterectomy, and was led by this experience to recommend it as the best operation when fibroids obstructed labour and also as an alternative to the ordinary Cæsarean section apart from fibroid tumours. In several other cases of pelvic fibroids complicating pregnancy he had found that the fibroids became elevated during the first stage of labour, and had enabled forceps to be used to complete delivery. He asked Dr. Routh whether there was much hæmorrhage before the ovarian and uterine arteries were tied and whether the elastic ligature was used.

Dr. WILLIAM DUNCAN approved of the details of the operation performed by Dr. Routh. He believed that abdominal hysterectomy with intra-peritoneal treatment of the stump was much less dangerous than any Cæsarean section except in cases of cancer of the cervix where he would prefer to treat the stump extra-peritoneally. He preferred to leave both ovaries instead of only one, as he had several times noticed that when one ovary was removed various unpleasant "menopause" symptoms supervened, although never so severely as when both ovaries had been removed.

Dr. PETER HORROCKS said he preferred to speak of Cæsarean section rather than of Sänger-Cæsarean because the evolution of asepsis had led many operators to abandon Sänger's main improvement, which was to sew the peritoneum completely over the deep sutures. Although he believed that Dr. Amand Routh had done quite the best thing in his case he did not think it was possible to formulate rigid rules for all cases, for it often happened that it was found best to do something quite different from what was intended before the operation was begun. Speaking generally, he preferred Cæsarean section to Porro's operation, sterilising the patient by snipping half an inch out of the middle of each Fallopian tube. This operation was, he considered, easier and safer for the patient. If possible, he always left both ovaries when performing hysterectomy, although he had never found that climacteric atrophic changes ensued if only one were left behind.

Dr. W. R. DAKIN believed that if one ovary were left behind after hysterectomy the effect was the same as if both were left. He agreed with Dr. Routh that the woman escaped certain risks if the uterus were removed instead of being merely sutured and the patient sterilised, and alluded especially to the risks of infection of the peritoneum through an imperfectly sutured wound and of adhesions between the uterine and abdominal wounds which might cause strangulation of the bowels. If the woman wished to have a family, all members of which were to be delivered through the abdominal wall, it was another matter. He had observed no greater shock after supra-vaginal hysterectomy in these cases than after an ordinary Cæsarean section, but agreed that it was wise not to decide how the operation was to be finished till the child was actually extracted from the incised uterus. He had recently operated with successful results to both mother and child where the true conjugate was only two and three-quarter inches. In a previous pregnancy labour had to be induced at the sixth month. The patient agreed to an abdominal operation but wished at the same time to be sterilised. At the operation, after extracting the child, he found the uterine vessels were standing out so clearly and were so easy to ligature that he decided it would be a much shorter procedure to remove the body of the uterus, treating the stump by the retro-peritoneal method, than to suture the uterine wound and to ligature and excise a part of each tube. He thought this would be the decision most often arrived at under similar circumstances.

Dr. HERBERT SPENCER agreed that the best operation had been done in this case and he had himself performed Porro's operation under similar circumstances eight years ago. While the intra-abdominal treatment of the stump shortened the convalescence and lessened the risk of hernia it did not always prevent septic peritonitis, by infection of the ligatures through the vagina (Klotz), nor the risk of adhesion of bowel to the seam causing intestinal obstruction, which had occurred in one of his own cases. He did not consider that Porro's operation should be done in all cases of permanent obstruction, such as contracted pelvis. He much preferred the conservative Cæsarean section. He would, however, have nothing to do with sterilisation by tying or cutting the tubes, which, besides exposing the patient to additional risks, was very unreliable in its effects and was at least debateable from the moral standpoint. The conservative Cæsarean section was a very successful one and left no stump for intestines to adhere to, the wound in the puerperal uterus lying up against, and becoming adherent to, the abdominal wall, so that in a subsequent operation the peritoneal cavity was sometimes not opened at all. He had recently performed Cæsarean section under local anæsthesia upon a patient whom he had delivered by Cæsarean section twice previously. As both the children thus delivered had subsequently died the advantage to the mother of having a third, and this time a very healthy, child was obvious. He had also successfully repeated Cæsarean section in another case.

Dr. COLLINGWOOD ANDREWS had had opportunities of comparing the progress of cases of hysterectomy during pregnancy where both the extra- and intra-peritoneal methods of treating the stump had been tried and greatly preferred the latter method.

Mr. A. C. BUTLER-SMYTHE thought that the operation performed by Dr. Routh was only possible in a hospital or where skilled assistance was obtainable. Wherever a Porro's operation was required, as in cases of fibroids, he considered the retro-peritoneal treatment of the stump far preferable to the old method, but he would leave the precise details of the operation to be decided when the abdomen was opened and the child extracted. That was also the time to consider whether the woman should be allowed to run the risk of another pregnancy.

Mr. J. H. TARGETT said he considered that a non-sterilising Cæsarean section was very rarely justifiable, while between a supra-vaginal hysterectomy and a Cæsarean section with sterilisation the balance would usually be in favour of hysterectomy, because it could be more rapidly performed and prevented the risk of hæmorrhage and subsequent sepsis. When the pregnancy was complicated with fibroids the advantages of supra-vaginal hysterectomy were obvious. As evidence of an additional risk in the after-history of cases where Cæsarean section without sterilisation had been done, he showed a specimen of a uterus which he had removed from a woman who had had Cæsarean section performed by him two years and a half previously for impacted shoulder presentation. When re-admitted she was in a state of collapse and when the abdomen was opened the child and placenta were found free in the peritoneal cavity, and there was a large rupture in the anterior uterine wall along the scar of the previous operation. The patient fortunately recovered.

The PRESIDENT believed that the retro-peritoneal operation was best provided that, as in the present case, the obstetrician had already performed it more than once on non-pregnant subjects and in hospital practice with plenty of assistants. Country practitioners with large midwifery practices but without experience of abdominal section have, as in a case within his own knowledge, had excellent results after the old Porro-Cæsarean operation, which was easy and could be done quickly. On that account Lepage performed the old operation in a hospital on a case of labour at term complicated by fibroids where there was free hæmorrhage, saving mother and child. Weiss and Schuhl reported the removal of the uterus in two cases of spontaneous rupture during labour occurring in a hospital. In one case the elastic ligature and pins were used and the patient recovered; in the second, which was lost, the retro-peritoneal operation was undertaken, but this case was septic. Panhysterectomy had the disadvantage of being yet lengthier than retro-peritoneal hysterectomy.

Dr. AMAND ROUTH, in his reply, agreed that the nomenclature was not altogether satisfactory, but thought that all cases of hysterectomy during late pregnancy (except panhysterectomy) were of the nature of a "Porro," the treatment of the stump being a detail capable of many renderings. He did not consider that the old "Porro" operation was suitable for cases of advanced cancer of the cervix owing to the great strain on the friable supra-vaginal cervix, which would almost certainly give way. He did not think it made any difference to the patient's after-history whether one or both ovaries were left. Most of the speakers had, with certain reservations, approved of his view that hysterectomy was in most cases preferable to Cæsarean section with sterilisation, and, as the President stated, if haste was essential the old "Porro" was indicated, otherwise the modern retro-peritoneal hysterectomy. Dr. Herbert Spencer's contention that wherever possible Cæsarean section without sterilisation should be performed, so as to allow another pregnancy to occur, was not in his opinion justifiable. The patient might at full term be far away from skilled assistance and would, moreover, run all the risks mentioned in his paper both during the puerperium and subsequently. The adhesions which Dr. Spencer stated occurred between the uterine and abdominal incisions constituted one of the dangers and involved the risk of intestinal obstruction. He preferred catgut to silk for suturing the muscle of the stump, owing to its quicker absorption, which therefore caused a smaller chance of subsequent infection. He had not found the elastic ligature necessary but had quickly tied or clamped the uterine vessels.

The following specimens were shown:—

Dr. G. F. BLACKER: Frozen Sections of an Early (ten weeks) Pregnant Uterus.

Dr. PETER HORROCKS: A Pregnant Uterus with Fibroids removed at the fifth month by Abdominal Hysterectomy.

Mr. J. H. TARGETT: A Pregnant Uterus Ruptured at Full Term through the Scar of a Previous Cæsarean Section removed by Abdominal Hysterectomy.

Dr. AMAND ROUTH: A Pregnant Uterus with Fibroids removed at Full Term by Abdominal Hysterectomy.

Dr. WILLIAM DUNCAN: Multiple Myxomatous Polypi from the Cervix Uteri.

OPHTHALMOLOGICAL SOCIETY.

"Holes" at the Macula.—Optic Nerve Tumour.—Pseudo-Glioma.—Alveolar Carcinoma of the Eyelid.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on July 6th, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Dr. F. M. OGILVIE read a paper on one of the results of Concussion Injuries of the Eye—"Holes" at the Macula. He had collected all the published cases presenting this lesion and he divided them into two large classes: (*a*) those in which there was no detachment of the retina, and (*b*) those in which detachment was present. He showed lantern slides of the appearance of the fundus in all these cases which invariably followed concussion injuries, such as blows from blunt objects, from stones thrown from catapults, and one most interesting case he had previously shown to the society in which the injury was due to a bullet which apparently hit the back of the eye in passing through the back of the orbit. He advanced several theories to account for the holes which, as a rule, were about one and a half dioptres in depth. He summarised the conditions brought about as follows: (1) the lesions were definite and central; (2) they were the direct result of violence; (3) the injury was permanent; (4) the general disturbance of vision was not great; and (5) it was the result of concussion injury only.—Mr. ADAMS FROST endorsed all that Dr. Ogilvie had said regarding the appearance of the lesion, and in view of the fact that no case had as yet been examined pathologically he suggested that possibly a similar condition might be brought about by a like injury in the eyes of animals or in eyes recently excised.

Mr. C. DEVEREUX MARSHALL read further notes of a case of Optic Nerve Tumour previously reported to the society in November, 1899. The patient was a woman, aged 46 years, upon whom he operated at the request of Dr. Poulett Wells on Nov. 30th, 1897, when the contents of the orbit were thoroughly removed. She remained in very fair health until shortly before her death, which took place on May 4th, 1900 (two and a half years later). Owing to the kindness of Mr. Austin Reynolds who attended her up to the time of her death, which occurred very suddenly, Mr. Devereux Marshall was enabled to obtain a post-mortem examination. The necropsy was made on May 6th and the following was the condition found. On removing the calvaria the middle meningeal vessels were found to be distended and the Pacchionian bodies were very large. The cerebral convolutions were very much flattened. The optic chiasma had entirely disappeared and its place was occupied by a large diffuse and very soft tumour of about the size of a bantam's egg. So soft was it that its actual limits could not be defined, and the greater part of it could easily have been washed away with a moderately strong stream of water. The centre of the growth was the right optic tract and it spread along the chiasma, involving the optic tract and optic nerve on the left side, both of which were considerably enlarged. The tumour reached the pons on both sides, invaded the lateral and third ventricles, and on the left side the optic thalamus and corpus striatum. The growth was so very diffuse that it appeared that the third, fourth, fifth, and sixth nerves on both sides were more or less included in it. On both sides the under surfaces of the temporo-sphenoidal lobes were invaded. The tumour was still further broken down by recent hæmorrhage in the vicinity of the left optic tract. No separate deposits were found in the brain and the growth had evidently spread by continuity only. Briefly, the neoplasm seemed to be due to an immense overgrowth of the connective tissue framework of the nerve, mainly the neuroglia, but also of the more fibrous prolongations from the pial sheath. The optic nerve on the opposite side was much enlarged and on examining it microscopically the sections were seen to present precisely similar appearances to those on the right nerve which was described in the first paper. Mr. Devereux Marshall added that in the last volume of the Transactions would be found a paper by Bullar and himself, the basis of which was a case of optic nerve tumour somewhat similar to that described that evening, and at the present time (three years after removal) the patient was alive and well. In that paper the question of prognosis was fully discussed and the conclusion arrived at from published cases was that the disease, although of not

a very malignant type, could by no means be considered innocent and it was advisable to remove it as thoroughly as possible. This remark was justified by the present case where, although removed as completely as possible, the nerve was affected further back than the orbit and this was, of course, the way by which the growth reached the brain.

Mr. PERCY FLEMMING read a paper on three cases of Ophthalmitis (Pseudo-glioma) in Children. Case 1 recovered after a four months' illness, the main symptoms being irregular pyrexia, vomiting, head retraction, and diarrhœa. There was a history of convulsions and ear discharge, but no history of syphilis or acute specific fever. Case 2 died with typical posterior basic meningitis and pus in the right middle-ear. (This patient had an attack of chicken-pox four weeks after the eye became affected.) Case 3 died after an illness very similar to that of Case 1 and post mortem was found to have basic meningitis; the middle-ear was healthy. These cases, considered in relation with others published, might be taken to indicate that meningitis was the common cause of this particular form of ophthalmitis, and, further, that middle-ear disease was a likely cause of the meningitis. The following objections were urged against this view: (1) the fact that these cases in children rarely ended fatally; (2) pseudo-glioma was a rare complication of posterior basic meningitis, as was also optic neuritis; and (3) the usual unilateral character of the affection. Mr. Flemming considered that the eye condition was part of a septicæmic or pyæmic process which in most cases was limited to the eye, such cases recovering, whilst in others the meninges might be affected by the same process, these cases terminating fatally. The otitis might be the starting-point of the infection, and in any case of ophthalmitis (pseudo-glioma) it was most important to have the ear examined and even to puncture the membranes though apparently healthy.

Mr. KENNETH SCOTT and Mr. JOHN GRIFFITH contributed a paper on a case of Alveolar Carcinoma of the Eyelid which was removed from an Egyptian. The specimen on examination proved to be a carcinoma of the Meibomian glands.

The following cases and card specimens were shown:—

Mr. E. W. BREWESTON: A case of Pseudo-glioma.

Mr. W. T. HOLMES SPICER: Sections of Conjunctiva from a case of Spring Catarrh.

Mr. W. H. JESSOP: Tuberculous Ulceration of the Conjunctiva.

Mr. W. ADAMS FROST: Peculiar Crescentic Opacities in the Cornea.

Mr. TREACHER COLLINS: A case of Congenital Notch in each Lower Lid with Defective Development of the Malar Bones.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on June 23th at 20, Hanover-square, W. In the absence of the President, Dr. Payne, Vice-President, took the chair.—Dr. Eddowes showed a Case for Diagnosis. The patient was a girl, aged about 20 years, with a chronic unilateral linear non-pigmented papillomatous eruption starting from the vertebral line between the third and fourth dorsal spines and extending with some lapses of continuity across the right shoulder and down the extensor surface of the right arm on to the dorsum of the hand. It had the appearance of congenital neuropathic papilloma, but there was a very clear history that the eruption began on the hand only at the age of 10 years and was at first completely healed by treatment for eczema, which was the early diagnosis. The eruption had remained in its present condition for some eight years.—A majority of those joining in the discussion considered the case to be of the nature of ichthyosis hystrix, anomalous in its distribution and commencement.—Dr. Stowers showed: (1) A case of Hydroa Æstivale with Photographs of an analogous case previously shown; (2) Local Tuberculous Infection of the Skin in a child aged two and a half years; and (3) a Papulo-squamous Eruption on the Palms of the Hands with ulcerating nodules at the right angle of the mouth and under the right ala nasi, probably syphilitic in origin.—An interesting discussion took place on Unusual Sources of Primary Infection.—Mr. Hitchins showed a case of Maculo-anæsthetic Leprosy in a boy, aged 16 years, a native of South America. The disease was progressing rapidly.—Mr. Pernet exhibited a Microscopic Preparation from the case of Rodent Ulcer shown at the last meeting.—The next meeting of the society will be in October.

Reviews and Notices of Books.

Les Défenses Naturelles de l'Organisme. (*Natural Defensive Mechanisms of the Organism.*) Par M. le Professeur A. CHARRIN. Paris: Masson et Cie. 1898. 8vo, pp. 319.

THESE 21 lectures by Professor Charrin deal with a subject which is receiving much attention at the present moment. After some introductory remarks the author discusses the relationship of the alkalinity of the body fluids to the defensive mechanisms of the individual. In Lectures III., IV., and V. ductless glands with their internal secretions come under review. Thus a full account is given of the functions of the thyroid body and the effects produced by its removal. The relation of the suprarenal bodies to Addison's disease is also discussed, as well as the rôle played by these organs in the infections and their action upon the circulation. Lastly, the important relations of the spleen to the composition of the blood are described and the experimental work in connexion with the spleen and infection is reviewed. Lecture VI., in which are considered the effects of an increased body temperature and the methods possessed by the individuals to counteract them, is of considerable interest. In Lectures VII. to XVI., inclusive, the parts played by various organs in protection against disease are discussed. The stomach affords a striking example. The rarity with which this organ is the seat of infection proper is well recognised. Much importance has been attached in this respect to the acidity of the gastric juice, but it would appear that the active principles of this secretion can also neutralise some toxins. The relation of disease of the pancreas to diabetes is also a subject of special interest. The important part played by the liver in the protective mechanisms of the body are set out in much detail. Under the generative system the question of the internal secretions of the ovaries and testes is discussed. The methods by which harmful products are got rid of by the various organs of elimination deserve and receive here much attention. The subject of the toxicity of the urine is fully considered under this section. The protective mechanisms provided by the nervous system are largely of a reflex character. The last lecture deals with phenomena outside the individual, such as light, warmth, vaccines, &c., which assist in protecting him against disease. The path of entry of micro-organisms and the means of combating them are specially considered. The author points out that it is only when the various defensive mechanisms are defective or have deteriorated that the agents of disease enter upon the scene. This volume of lectures by Professor Charrin is not only extremely interesting, but it is instructive and very suggestive. It brings together in compact form topics upon which the writings are mostly scattered. The subject itself appeals to a wide circle of readers for it interests not only the physiologist and pathologist but also the clinician.

Les Ptoses Viscérales (*Estomac, Intestin, Rein, Foie, Rate*). *Diagnostic et Nosographie* (*Enteroptose, Hépatisme*). (*Displacements of Viscera* (*Stomach, Intestines, Kidneys, Liver, and Spleen*). *Diagnosis and Nosography—Enteroptosis, Hepatism.*) Par FRANTZ GLÉNARD. Paris: Felix Alcan. 1899. 20 francs.

IN this large octavo volume of close on 1000 pages Dr. Glénard gives us his experiences of 20 years of practice at Vichy based on the personal investigation of more than 10,000 patients. The avowed intention of the work is to establish enteroptosis as a definite morbid species, which is shown to include a vast number of diseases at present classified under the several heads—dyspepsia, neuropathies, neurasthenia, diseases of the stomach and intestine, and uterine affections. The enormous importance attributed by the author to functional and other

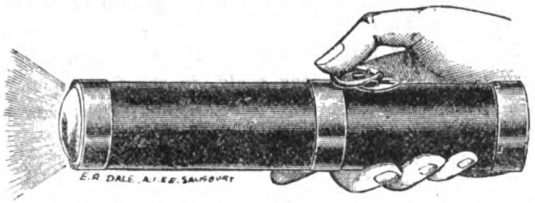
disorders of the liver in the causation of many of these conditions is evidenced by the fact that more than half the volume is devoted to the consideration of the disorders and displacements of this organ. In this clever and charmingly written book the reader will find a masterly if somewhat diffuse description of the physical examination of the abdomen in its minutest details. The chapter dealing with palpation of the intestine and the recognition of functional atonic narrowing of the large intestine (*entérosténose*) is particularly interesting and suggestive. The signs and symptomatology of the disorders and displacements of the stomach and of dislocations of the kidneys are fully treated, and among numerous clinical records of illustrative cases will be found a valuable epitome of all the recorded cases of floating liver (*hepatoptose*) as well as a series of 80 cases in which ptosis of the liver was associated with moveable kidney. We must refer the reader to the original for the deductions which Dr. Glénard draws from the rich store of clinical observations which he has so carefully collected and analysed.

Anatomie Clinique des Centres Nerveux. (*The Clinical Anatomy of the Nervous Centres.*) Par M. le Dr. GRASSET. Paris: J. B. Baillière et Fils. 1900. Pp. 96.

A KNOWLEDGE of the anatomy of the nervous system is of the first importance to the proper understanding of nervous disease, hence this small work by Dr. GRASSET, who is himself a well-known neurologist, should prove to be of considerable value. In Part I. the neuron, together with the systems which it forms and its connexions, are fully considered and the whole subsequent treatment of the subject is based on the neuron conception. In the description of the superior and inferior psychical centres this doctrine is even applied to the processes underlying the most strictly psychical phenomena. A short account is also included here of the development of the nervous system, as well as some remarks on the subject of myelinisation, or the development of the medullary sheath. In Part II. the motor and sensory cerebro-medullary paths, both direct and indirect, are described. The remaining sections are allotted to the central nervous apparatus for vision, hearing, taste, and speech, and for the circulation, secretions, respiration, and digestion. This small book will be found to contain much useful information which will facilitate the study of nervous disease.

LIBRARY TABLE.

Laboratory Note-book for Chemical Students. By VIVIAN B. LEWES and J. S. S. BRAME. London: A. Constable and Co. 1900. Pp. 170. Price 4*s*.—Chemical work of any kind is of very little use to the student unless it is accompanied by intelligent and systematic note-taking. If this is true of the theoretical portion of chemistry it is doubly so in the case of experimental work, and Messrs. Lewes and Brame are to be congratulated in their attempt to supply a suitable book for the purpose. In their preface the authors state that their Note-book has been compiled without reference to any particular syllabus or examination and that it is intended to cover such practical work as a student should be familiar with if he is to have a good groundwork in the subject of practical chemistry. Although not written in any sense for a special examination there is no doubt that it will be found extremely useful to candidates for the Preliminary Science Examination London, and, indeed, for any other examinations where the preparation of certain gases and salts together with a little elementary volumetric analysis are a *sine quâ non*. The pages are interleaved throughout for the students' own notes. A section of a more advanced character at the end of the book deals with the preliminary examination of water, oils, and explosives, written more especially for the benefit of naval, engineering, and mining students.



Gynæcological Nursing. By G. A. HAWKINS-AMBLER, F.R.C.S. Edin. London: The Scientific Press, Limited. 1900. Small crown 8vo. Pp. 93. Price 1*s*.—This little book contains a very practical and good account of the special details of gynæcological nursing. The duties of the nurse are given clearly and succinctly and cannot fail to be of service to those who are engaged in such special work. We are surprised to see, however, in the midst of so much that is good a description of the method of passing the catheter by touch, a custom which we thought was fast becoming obsolete. The observations of the author upon the personal hygiene and the special qualifications required from nurses engaged in gynæcological nursing are especially apt and to the point.

The Bubonic Plague. A Popular Lecture by Professor ANDERSON STUART.—Dr. Anderson Stuart has republished in pamphlet form a lecture recently delivered by him in Sydney. It is a clear and brief account of the plague, going as far into the etiology and pathology as the popular nature of the lecture allows, and explaining with a remarkable absence of technical phraseology the work of Yersin, Haffkine, and others. We hope that the lecture has obtained the wide circulation that it deserves, for undoubtedly it is good that people should know the measure of the risk that they run by the non-observance of medical regulations.

New Inventions.

THE "EVER READY" ELECTRIC LIGHT.

THIS is a handy little lamp, made in various sizes from three and a half to five and a half voltage and worked by a dry cell. Contact is made by pressing a ring down upon a spring. The whole is inclosed in a neat case and the cell is stated to have a life sufficient to give from 6000 to 8000 lights before requiring renewal. This of course is a hopelessly vague statement, for the life of the cell will entirely

depend upon the length of time for which the lamp is kept burning. The appliance, however, will be found convenient. It is made by Mr. E. R. Dale, 89, Fisherton-street, Salisbury. Mr. Dale, we see, calls himself a medical electrician as well as an electric light contractor. If this means only that he makes electrical medical apparatus—and we presume that Mr. Dale is not a medical man—he should state the fact in different words.

THE CAMBRIDGE SENTINEL PATENT DOMESTIC MILK STERILISER.

THIS is an ingenious invention for ensuring that milk when being sterilised by heat shall not be boiled—in other words, when the temperature reaches 185° F. the process of heating is stopped. The steriliser is made in two forms. In the one the heating is done by means of a gas stove in which upon the temperature reaching 185° the gas is automatically cut off. The other form which is for use with an ordinary fire cannot, of course, cut off the heat-supply, but when the desired point is reached a bell rings and so calls attention to the fact that a temperature of 185° has been reached. The apparatus is extremely simple and there are no complicated parts to get out of order. The apparatus can be obtained from the Sentinel Co., Limited, Cambridge. The saucepan is made of enamelled iron and the prices vary from 17*s*. 6*d*. for a six-pint pan with stove to 6*s*. 6*d*. for a one pint pan without stove for use on a fire.

THE LANCET.

LONDON: SATURDAY, JULY 14, 1900.

IN order to get a clear notion of the situation which has been brought about by Mr. BURDETT-COUTTS'S letter in the *Times* of June 27th last it is necessary to enter upon a brief description and recapitulation of what has since taken place. The main facts are, in our opinion, sufficiently clear. There was a serious outbreak of enteric fever among the troops in the Orange River Colony during the month of April, and we are content to accept in the meantime, and until it has been disproved, Mr. BURDETT-COUTTS'S statement in regard to what he saw at Bloemfontein on April 28th and subsequently. Bloemfontein, it will be remembered, was occupied by our troops on March 13th. They arrived there in a physically exhausted condition after a series of forced marches and after having altogether distanced their supplies. They became dependent upon a thin and precarious line of transport. An outbreak of enteric fever occurred and the medical service, overwhelmed by the amount and explosive nature of the epidemic, for a time had not the means of coping with it. This gave rise to the overcrowding and the lamentable suffering and occurrences described by Mr. BURDETT-COUTTS. We may set aside all the testimony of correspondents and others descriptive of their experience at other times and places as irrelevant and therefore worthless. The only questions are whether the emergency could, in the first instance, have been prevented, and secondly, whether, having arisen, everything was afterwards done as promptly as practicable to meet it. With regard to the second question Mr. BURDETT-COUTTS plainly implied that in his opinion such was not the case, and he has urged that if one day's trains on the railway had been utilised for getting up hospital stores the whole position of the sick and wounded would have been saved. This is a matter that has to be thoroughly gone into.

In the debate in the House of Commons on June 29th which followed upon the publication of Mr. BURDETT-COUTTS'S letter Mr. WYNDHAM gave a very able and lucid statement in explanation of affairs in South Africa. He spoke in defence of the Government and those concerned as far as the information in his possession enabled him to do so. Mr. BALFOUR, in a speech which was not devoid of asperity, held that the charges raised by Mr. BURDETT-COUTTS involved a question of transport. After Lord ROBERTS had made his remarkable march to Bloemfontein, said Mr. BALFOUR, he had to depend upon a very precarious transport, and the preventability or inevitability of the enteric fever among the troops turned upon how Lord ROBERTS or his subordinates used this transport. Here we may remark that, as far as we can see, there is really no occasion for any persons to shelter themselves behind the well-known popularity of Lord ROBERTS. It is a question of fact about which the commission going to South Africa will have to inquire. If the army medical authorities failed to represent the pressing urgency of the case they must of course take the consequences; whereas if the military authorities assumed the responsibility of overruling them and of using the transport in such a way as to be of no service to the medical service no blame can obviously in that case be attached to the medical service. It is only fair to say that there seems to be no question that the troops were in a miserable plight on their arrival at Bloemfontein—they and their horses were half-starved. Soldiers cannot fight unless they are properly fed and supplied with ammunition, and unless the military machine is in an effective state the safety of the whole force, sick and well, may be jeopardised. It is clear that in an emergency of this kind the medical equipment would have to rank after and not with the food-supply of an army.

Next came the appointment of a commission with the following reference: "To report on the arrangements for the care and treatment of the sick and wounded during the South African campaign." It should be added that Mr. ARNOLD-FORSTER asked, "Does the reference include the power of inquiry into the organisation of the Army Medical Department?" and was told in reply that the question was not referred to the commission but that no doubt the finding would have a bearing on it. The names of three commissioners were originally proposed—viz., Lord Justice ROMER; Dr. W. S. CHURCH, the President of the Royal College of Physicians of London; and Dr. D. J. CUNNINGHAM, Professor of Anatomy and Surgery, Trinity College, Dublin. No objection was raised on the score of their ability. The selection of a lawyer of the great eminence and business qualifications of Lord Justice ROMER, accustomed to and able to instruct those associated with him in the laws of evidence and in the testing and sifting of it, was felt to be very appropriate, while the official positions of the two medical men spoke for their reputations. But the feeling of the House was strongly against having the commission so small, and many Members held it to be a serious mistake on the part of the Government to have allowed a preponderance of medical men on it. Mr. BALFOUR attempted to support his original proposition, but had to yield the point in deference to the opinion of the House and the commission of three was increased to five. There can be no possible objection to the increase of the lay element on the commission, although we cannot see why members of the medical profession should not bring absolutely honest and impartial minds, together with common sense and experience of life, to the task. We have no desire to see any undue preponderance of the medical element on the commission. But we are not satisfied with its constitution and, such being the case, we are bound to state our reasons.

In the first place, there is such a thing as sacrificing efficiency to a fastidious sense of impartiality. There is no representative of the Army Medical Service on the commission who could, by his technical knowledge and

experience of army life, keep the commission informed on all points connected with the organisation, equipment, system, and methods of procedure adopted on field service, the reasons for their existence, and how far they are in conformity or not with those of all other European armies. It may be said that there was no necessity for such an appointment seeing that there were any number of medical officers in South Africa who could be summoned to give their evidence on such matters. This is practically tantamount to saying that the commission would be learning their business during their inquiry, and this is a thing which too many of our commissions are content to do. The special knowledge of a medical officer of ability and independence would be of immense value in facilitating the business of the inquiry and in indicating the nature and bearing of many of the questions that will have to be put. If no such officer is appointed on the commission we think it very desirable that such an officer should be called in as an assessor who need take no part in the deliberations and need not sign the report. If the commission can make any suggestions for improving the organisation of the Royal Army Medical Corps, or for providing a better hospital service than the present one, without gravely prejudicing the mobility of the army on a campaign, we can answer for it that there is no section of the community which will be more grateful to them than the medical profession. Any such suggestions could probably be more thoroughly considered and worked out subsequently. With this very practical end in view it seems to us that the aid of a man with some army experience is an essential matter.

Lord Justice ROMER is, as we have said, an unexceptionable choice. Dr. CHURCH, occupying the highest professional position as President of the Royal College of Physicians of London and as a physician on the staff of a hospital like that of St. Bartholomew's, in addition to enjoying the reputation of being an excellent man of business, unites all the necessary qualifications for the task before him. Concerning the third commissioner as yet selected we have some delicacy in expressing an opinion. No one can recognise more fully than we do the great reputation and scientific attainments and ability of the Professor of Anatomy and Surgery in Trinity College, Dublin, but we feel sure that we shall not be misunderstood in saying that the inquiry in South Africa does not seem to us to be one calling for his special gifts. Rather it demands the exercise of qualities of another kind and occupying a distinctly lower level, and not necessarily a scientific one even. With all possible respect for Professor CUNNINGHAM we must confess that we do not see his especial claim to be a commissioner, and we say this without laying any stress upon his official connexion with the Army Medical Service to which attention has been pointedly drawn. But in addition to the present commissioners we think it highly desirable that the services of a traffic manager of one of our great railways should, if possible, be secured. Such a man is sure to be a man of business capacity and common sense or he would not be where he is—in the position of traffic manager—and his practical experience and intimate acquaintance with systems of railway organisation would be invaluable in an inquiry of this kind. We hope that one at least of the two commissioners to be added will be a man of tried capacity in business affairs, preferably in railway transport.

SINCE the well-known description in the "Surgeon's Daughter" by Sir WALTER SCOTT of the medical practitioner, "from whom Scotland reaps more benefits and to whom she is perhaps more ungrateful than to any other class of men, excepting her schoolmasters," there have been few more eloquently simple accounts of the lot of the Scottish village practitioner than is contained in a memorial to the Local Government Board of Scotland, signed by 40 medical officers of the more remote parishes of the Highlands and Islands of Scotland which we publish in our columns this week (page 129). "Besides," says Sir WALTER SCOTT, "attending to such cases as the village may afford he is day and night at the service of anyone who may command his assistance within a circle of 40 miles in diameter, untraversed by roads in many directions, and including moors, mountains, rivers, and lakes. For such work the village doctor receives at best a very moderate recompense, often one which is totally inadequate, and very frequently none at all." No wonder that MUNGO PARK told Sir WALTER SCOTT that after trying both courses of life he preferred "travelling as a discoverer in Africa to wandering by night and day the wilds of his native land in the capacity of a country medical practitioner."

The memorial of the Scottish medical officers of the more remote Highlands and Islands shows that there is little improvement in the position of the medical man as compared with what it was in MUNGO PARK'S time. The wealth of Scotland has enormously increased. She has spent millions of money in the vindication of religious sentiment or principle. But she has made little advance throughout these remote regions in the treatment of her poor or in the remuneration of the medical men who attend them. This subject is not new to us. We have on several occasions tried to direct the attention of the medical profession of Scotland, as well as that of her statesmen, to the lamentably defective provision in these districts for the care of the poor in respect of nursing and medical attendance. There is, for example, no isolation whatever of infectious cases. The neglect of such provisions by the responsible authorities of Scotland has had a demoralising effect on the people themselves—religious and decent as they are—so that on some occasions and in certain districts those affected with fever have been left to die alone, forsaken by their very relations and with none to give them a drink of water or, in the event of death, to put them into their coffins. Only the medical man. And we cannot altogether acquit the profession itself of blame. A little more assertion of its own claims and a little more publicity thrown upon the discreditable plight of the sick in their wretched and unhygienic homes would have been justified, and might have deprived the authorities of Scotland, imperial or municipal, of any excuse that they may now have for so long leaving enormous districts in ignorance of sanitation and with very imperfect means of battling with tuberculosis and infectious diseases. There is one difference between the Scotland of to-day and

that of Sir WALTER SCOTT and MUNGO PARK. In their time the organised system of relief by poor-laws scarcely existed. Men like the late Dr. CHALMERS believed in the sufficiency of the principle of humanity acting voluntarily and for the most part through churches. But now the legal system of relief of poverty and sickness has been generally introduced, and we must attribute its defects mainly to the municipal and State authorities. Such authorities will doubtless argue that they only represent the community for which they act. And they will argue rightly. Nobody can doubt that if half the enthusiasm were shown by the people of Scotland in the provision of proper medical care for the poor in remote parts that is shown in providing for their spiritual wants their condition in respect of preventable sickness and mortality would be very different from what it is, and the medical men who wander over these wide districts would be more respected and better remunerated than they are.

The memorial may be taken as a sign that the medical officers themselves who are the agents of this system of relief are beginning to realise its defects. There can be but one opinion as to the hardness of their lot, the responsibility of their duties, and the inadequacy of their pay. Liable to calls in all weathers, in all seasons, over areas of 30 or 40 miles, sometimes unable to return home the same night, and with little chance of earning more than from £20 to £50 a year beyond their official parochial salary, their case is indeed entitled to consideration in many more respects than that which they specify. They ask only for the provision of a locum-tenent for a month, which would enable them to seek rest and refreshment in an annual holiday. We endorse every word of their memorial, only finding it too restricted in its points of complaint. The sick poor of these remote regions will not be properly treated until much more is done to improve the medical officer's position than is implied in supplying him with a locum-tenent. His whole status needs improvement, coupled with the security of tenure of office. Meantime he has made the most modest request possible for an advantage already conceded to dispensary medical officers of Ireland. We cannot doubt that it will be granted. The demand is the more reasonable as the value of locum-tenents has risen much of late, and, indeed, has reached a point beyond the means of the underpaid officers of the Scotch Poor-law. We have only to repeat that they owe it to themselves and to the poor of these districts to ask for many other improvements in their position beyond the solitary one included in their memorial.

EVER since the differentiation of the disease usually known as rötheln, or German measles, from scarlet fever and measles was first attempted in Germany towards the end of the eighteenth century various and conflicting views have been held by the medical profession as to its essential nature and clinical manifestations. It must appear obvious to any unprejudiced observer, as was suggestively pointed out by the late Dr. HILTON FAGGE, that the severe and frequently fatal affection described by PATTERSON of Leith in 1840, following the earlier German writers, and later by AITKEN and COPLAND, can have but little in common with the mild disorder described by THOMAS in ZIEMSSEN'S *Handbuch* some 30 years afterwards, which is more in accord with the observations of writers of the present day. So contradictory are the two accounts that it is impossible to regard them both as applicable to the same disease. Admitting, however, the general appropriateness of this modern conception of rötheln as we know it to-day we are confronted with the fact—and it is a most unfortunate one—that considerable discrepancies occur in the clinical descriptions of the disease emanating from different though equally competent observers. In other words, there exists even at the present day an undoubted want of agreement as to what constitute the distinctive symptoms of rötheln. In its clinical appearances the affection presents certain features which closely simulate both scarlet fever and measles. For this reason rötheln has been variously held to be a modified form both of measles and of scarlet fever, as well as a hybrid of the two infections. Each of these views is now regarded as untenable and the disease for some years past has been almost universally held to be a specific entity, having just as much claim to separate recognition as either measles or scarlet fever. We publish this week a communication from Dr. CLEMENT DUKES of Rugby in which he brings forward what are undoubtedly cogent reasons for revising our views as to the position of rötheln. The exceptional opportunities for observing the exanthemata which Dr. DUKES has enjoyed for many years as responsible medical officer to one of our largest public schools, and the special interest which he is known to have devoted to the clinical interpretation of this particular disease, entitle him to speak with more than ordinary authority.

Dr. DUKES'S main contention is that under the term "rubella," of which the other synonyms authorised by the Royal College of Physicians of London in the last edition of the "Nomenclature of Diseases" are "rötheln," "German measles," and "epidemic roseola," there are included two separate infections, each of which is etiologically and pathologically distinct; though hitherto, mainly in consequence of the close similarity of their clinical appearances, they have been almost universally confused. Their occasional concurrence in epidemic form would doubtless contribute in some degree to this confusion by tending to delay their separate identification, as has certainly been the case in respect to rubella when it has prevailed simultaneously with scarlet fever or measles. If Dr. DUKES is right in his contention that two perfectly distinct diseases have hitherto been classed under the term "rötheln," both of which are capable of propagation and invariably "breed true," we must recognise the presence amongst us of an additional specific fever which, like other members of the group, while affording protection against a second attack, confers no immunity whatever against the infection of any other disease. Dr. DUKES does not claim any novelty for the idea that two separate diseases are classified under the name "rötheln"; indeed, he himself, writing in 1894, distinctly refers to it. Moreover, the Council of the Medical Officers of Schools Association in a recent circular suggested that certain groups of cases to which they applied the name "infectious roseola," being of a particularly mild character

and unattended with obvious catarrh or definite faucial or glandular involvement, were really distinct from rubella though usually confused with it. Dr. DUKES states that though the question had frequently presented itself to his mind he had signally failed to establish a single fact to sustain the hypothesis, but that increased observation and extended experience have now convinced him to the contrary.

Although by those who enjoy exceptional facilities for observing the course and development of infective diseases amongst the young this pronouncement of Dr. DUKES may not be altogether unexpected, we imagine that to the profession at large the addition of one more exanthem to the recognised list will come with something of a shock. Dr. DUKES provisionally names it the "fourth disease" by reason of its admitted resemblance to scarlet fever, measles, and rötheln, which are already sufficiently confusing. The increased possibilities of mistake which the addition of a "fourth disease" implies are more than counterbalanced by the light which it undoubtedly sheds on what has hitherto proved the greatest stumbling-block to diagnosis in this particular field—viz., the confusing resemblance which rötheln bears alike to measles and to scarlet fever. The fact is so well recognised that it is customary to speak of the "measles type" and the "scarlet fever type" of the disease. Now, according to Dr. DUKES'S proposition the cases of the scarlatinal type are not rötheln at all, but instances of another affection—viz., the "fourth disease." Dr. DUKES is unfortunately obliged to admit that its resemblance to scarlet fever is so close as to make its recognition occasionally impossible and that a series of cases may be necessary conclusively to establish the diagnosis. For this reason he believes that innumerable cases of the "fourth disease" have been ascribed to scarlet fever, a suggestion which, if true, is of considerable importance. Its differentiation from rötheln, too, is frequently very difficult owing to the similarity of their symptoms, and the difficulty is increased not only in consequence of their period of incubation being almost identical, but also by reason of the fact that the two diseases are sometimes locally concurrent.

Let us now briefly review the evidence on which Dr. DUKES bases his belief that these cases are essentially distinct from rubella or German measles. The rash, though closely resembling that of rubella during its later stage by reason of its presenting a diffuse puncto-erythematous appearance, differs from it in that it does not pass through a stage of morbilliform maculation but assumes the scarlatinal characters from the outset. Distinct redness and swelling of the fauces sufficient to give them a velvety appearance are usually present, though attended with but little, if any, faucial discomfort. The cervical lymphatic glands are somewhat enlarged and tender, but though the enlargement is more pronounced than in scarlet fever it is usually less conspicuous than is the case in rubella, in which disease it is not very uncommon for the patient to complain of tenderness of the cervical chain for several days before the rash appears. In most cases the patient desquamates freely, the epidermis being shed in small scales, but in occasional instances the peeling appears to be as copious and complete as it ever is in scarlet fever. The disease occurs in patients who have previously, even recently, suffered from undoubted rötheln. This constitutes the strongest argument of all. Indeed, it was from personal observation of an epidemic at Rugby School last March that Dr. DUKES became convinced of the separate nature of the two disorders. Out of a consecutive series of 20 cases which displayed the symptoms characteristic of this "fourth disease" no fewer than nine of the boys—that is to say, 45 per cent.—had previously suffered from rötheln, some of them within the previous 12 months. An interesting point confirmatory of its being distinct from rötheln is that while rötheln, like measles, tends to affect large numbers in a school, the disease in question, like scarlet fever, always occurs to a much more limited extent—a fact which tends to show that it is less infectious at an early stage than rötheln.

In the differentiation of the "fourth disease" from scarlet fever the main difficulty lies in the extraordinarily close resemblance which exists between their respective eruptions. In each case the rash is followed by free desquamation and, according to Dr. DUKES, in exceptional instances of the "fourth disease" the peeling may be as profuse and protracted as it is in any case of scarlet fever. It is stated that the degree of peeling bears no relation to the intensity of the pre-existent eruption. In this respect, then, the "fourth disease" differs from scarlet fever. We gather that Dr. DUKES would place also some weight on the following points as serving to distinguish the "fourth disease" from scarlet fever. The incubation is considerably more prolonged—viz., from nine to 21 days; whereas in scarlet fever it is usually two days and rarely exceeds five days. It is suggested that the frequent confusion of the two diseases in practice may be accountable for the misleading statements in some of the text-books as to the occasional prolongation of the period of incubation in scarlet fever. There is usually no pre-eruptive illness, the invasion being unattended with either vomiting or faucial discomfort. The pulse-rate rarely reaches 100. This is in marked contrast to the relatively rapid pulse of early scarlet fever. The fauces are simply reddened. They are never really inflamed even should the rash be intense, which is by no means uncommon. The tongue shows no definite peeling but cleans in normal fashion; hence the "strawberry" tongue is wanting. The cervical lymphatic glands are always enlarged and tender, but not to the same extent as they usually are in rötheln. The kidneys are not affected; neither albuminuria nor nephritis are liable to arise. No immunity is conferred against a subsequent attack of scarlet fever and the period of infectivity is said to last but from 14 to 21 days, though desquamation may proceed for several weeks longer. Such are the points which are mainly concerned in the clinical differentiation of the "fourth disease" from rötheln and from scarlet fever.

Dr. DUKES recognised as far back, at any rate, as 1892 that there exists a disease so closely resembling scarlet fever as to be frequently mistaken for it even when prevailing as an epidemic. This affection he at that time regarded as the scarlatinal variety of rötheln. Subsequently, in 1896, in connexion with a most confusing outbreak in a school which he investigated with striking ability and marked success, Dr. DUKES elucidated the

important fact that this disease, which closely simulated scarlet fever, was prevailing concurrently with that affection. Since neither disease afforded protection against the other, as evidenced by the fact that 32 per cent. of the patients developed both of them in turn, the inference was certainly justified that the disease which formed the subject of investigation was specifically distinct from scarlet fever. Again, as recently as March, 1900, as a result of his inquiries into an outbreak at Rugby School of what was apparently the same disease, Dr. DUKES found that no less than 42 per cent. of the boys attacked had previously suffered from rötheln—a fact which made it more than probable that the disease in question was quite distinct from rötheln. Two points, then, may be regarded as proved. First, that the epidemic investigated in 1896 was not scarlet fever; and, secondly, that the outbreak at Rugby School inquired into last March was not rötheln; but whether, as is believed by Dr. DUKES, the disease was in each instance the same is not, we think, so conclusively proved, although its demonstration constitutes an important link in the argument by which he claims to have established the specific independence of the "fourth disease." The question as to whether the Rugby epidemic of last March may not have been after all a mild form of scarlet fever is one which appears to present some claim for consideration, since a remarkable constancy of type is occasionally observed in connexion with a localised prevalence of the disease. Dr. DUKES admits that the illness resembled scarlet fever more closely than any series of cases he had yet seen, that he had never observed such extensive desquamation except in scarlet fever, that none of the patients had previously suffered from that disease, and that the length of incubation in these attacks could not be ascertained. The force of these objections cannot be altogether ignored. Moreover, the negative aspect of some of the symptoms described—viz., the absence of definite faucial inflammation and, under these circumstances, of definite peeling of the tongue, the return of normal temperature by the third or fourth day, the freedom from kidney complication, and the apparent lack of infectivity after the third week—are all consistent with mild scarlet fever. This point is one of considerable interest, since the infectivity of the later peeling after scarlet fever has been much questioned during recent years. Any advance in our knowledge of what is and what is not scarlet fever is a valuable step in the right direction as tending without doubt to enhance professional credit and promote the welfare of schools; in addition to which, as Dr. DUKES very rightly and with much force points out, if a more accurate diagnosis is competent to effect a curtailment by two-thirds of the period of isolation hitherto deemed necessary for many of the cases which we have been accustomed to regard as scarlet fever, the proportionate saving of inconvenience and expense to the community must of necessity be considerable.

Dr. DUKES offers the suggestion that the wide extension of scarlet fever which was observed throughout the country during the winter of 1892 and the spring of 1893 may have been really dependent on the epidemic prevalence of the "fourth disease," and in confirmation of this view he instances the low mortality which characterised the outbreak. So far as London is concerned this view is not supported, for though the numbers admitted into the metropolitan fever hospitals during 1892 and 1893 considerably exceeded those of any former years the death-rate showed no corresponding reduction. But having regard to the relatively large proportion of cases certified as scarlet fever which are now received into the public hospitals the question as to whether the period of detention might not in many cases be reduced by some two-thirds is one of municipal importance as directly affecting the pockets of the ratepayers, both in respect to maintenance charges and the necessity for providing further isolation accommodation.

Dr. DUKES has done good service to the profession, and indirectly to the public, by showing most conclusively that there exists a disease which so nearly resembles scarlet fever as to have been frequently mistaken for it even when the opportunity has occurred of observing a multiplicity of cases; but whether this affection is specifically distinct, and not a form of German measles as is currently believed, is a point on which we think it right to suspend judgment for the present. Further critical observation, however, of the points so clearly indicated by Dr. DUKES may ultimately succeed in establishing this proposition.

Annotations.

"Ne quid nimis."

THE NEW UNIVERSITY OF LONDON.

THE history of the various stages in the movement for the formation of a Teaching University in London in the place of an Imperial degree-giving establishment has been fully placed before our readers. A complete sketch of its various details from 1864 to the appointment of Lord Davey's Statutory Commission in August, 1898, will be found in our Students' Number of Sept. 3rd, 1898. The new statutes were sealed by the order of the Commissioners on Feb. 13th, 1900, and the regulations were ordered by the House of Commons to be printed on March 1st, 1900. The statutes and regulations have now passed through Parliament, and we congratulate the Commissioners on the thorough and rapid manner in which they have carried out their part of the work. We trust that the machinery recommended by the Commissioners will as rapidly come into being and so speedily complete its various duties. The Senators (16) elected by Convocation will probably be chosen in October.

PLAGUE IN TURKEY.

THE first case of illness which gave rise to an alarm of plague in Smyrna has already been described in THE LANCET of May 19th (p. 1456) and June 9th (p. 1672). It was on May 5th that Dr. Amado of Smyrna first saw the patient and he immediately notified the case to the local *médecin sanitaire*. On May 27th Dr. Corris, also of Smyrna, met with a second instance of suspected plague. The patient was a man, aged 23 years, who had a temperature of 40·5° C. (105° F.) and a pulse of 120 per minute; he suffered from intense headache, vomiting, mental apathy with inability to answer questions, flushed face, and an inguinal bubo on the right side of the size of a small egg and painful when touched. There was no apparent lesion which might have caused the bubo. On the following day (May 28th) the patient was

somewhat better, but on a more careful examination it was found that instead of one bubo there were four enlarged glands—one in Scarpa's triangle, two above Poupart's ligament, and one above the pubes. The two patients lived about 400 yards apart. On June 7th a third case of suspected plague was discovered, the patient being a lad, 14 years of age, a Mohammedan servant in a Mohammedan house in the Turkish quarter far from the neighbourhood of the previous cases. His symptoms were a temperature of 38° C., a pulse of 90 per minute, an enlarged gland in Scarpa's triangle of the size of a pigeon's egg and painful when touched, and three enlarged glands above Poupart's ligament. Although the symptoms were not pathognomonic of plague the patients were isolated outside the city on a hill at Kiatipoglu. On the first case being reported to the authorities at Constantinople the Inspector-General of the sanitary service and Dr. Nicol, the director of the Pasteur Institute at Constantinople, were ordered to proceed to Smyrna to make investigations. Dr. Nicol and Dr. Nouri Bey were unable to find plague bacilli in the enlarged glands of the patients, but cultures showed the bacilli after three days' growth, and the same cultures produced characteristic lesions in rabbits. On June 6th and June 11th the *médecin sanitaire* at Trebizond reported two suspected cases of plague, one a man, aged 70 years, a pilgrim just returned from Mecca, and the other, a girl, aged five years, the daughter of a boatman. There was no bacteriologist at Trebizond, but one has been sent there from Constantinople. The precautions taken by the authorities are limited to quarantine and nothing is being done to improve the sanitary condition of the towns.

PYORRHŒA ALVEOLARIS.

AT a recent meeting of the Royal Medical and Chirurgical Society Mr. Rickman Godlee drew attention to that condition of the gums which is termed "pyorrhœa alveolaris." The medical profession has so far given but scant attention to this distressing condition, and the gums as a possible focus of infection have been almost, if not entirely, overlooked. Conditions which lead to the loss of teeth at an early age owing to a gradual but progressive destruction of the periodontal membrane have greatly increased in recent years. This destruction of the periodontal membrane is, as far as present knowledge shows, due to an inflammation commencing around the necks of the teeth and spreading towards the apices. All the teeth may be affected by the disease or the condition may be limited to a few teeth or even to one. In some patients the disease progresses slowly, and although pus may be present in small quantities it is not easily recognised. In other cases the destruction of the periodontal membrane is rapid and accompanied by much congestion of the gums and a copious discharge of pus from the tooth-sockets. The constant swallowing of so much pus may give rise to infective gastritis and other conditions traceable to the presence of pyogenic organisms. The importance of this to medical men is obvious. In the four cases recorded by Mr. Rickman Godlee the absorption of the pus from the mouth seems to have played an important part in the causation of the conditions recorded, since on the flow of pus from the gums being checked the general condition of the patient considerably improved. Dr. William Hunter, too, has recently shown that there are strong reasons for believing that some cases of pernicious anæmia are traceable to absorption of septic and infective material from the oral cavity. Within the last few years an abundance of literature has appeared dealing with the etiology of this disease. In reading this through it is evident that the term "pyorrhœa alveolaris" is differently used by different writers. Some include under this term only that condition where suppuration is present (true pyorrhœa alveolaris), while others include all conditions where the gums are receding. Among the latter many cases are due not so much to a suppurative inflammation as to degeneration and atrophy of the tooth attachments. There is also a divergence of opinion as to whether the disease is local or general in its origin. If the majority of patients suffering from pyorrhœa be examined it will be found that they are the subjects of some diathesis, such as gout or rheumatism, or are suffering from conditions which tend to lower the general vitality of the tissues, more especially fibrous tissues. These conditions may be regarded as predisposing causes, the actual disease being started by some local irritant, such as the deposit of tartar, or an anhygienic condition of the mouth, or a badly fitting denture. When once the inflammatory process is started it is not difficult to understand that suppuration may take place when it is remembered that pyogenic organisms, more especially the streptococcus brevis, are present in nearly all mouths in which there is caries. Dr. Miller of Berlin has made a careful bacteriological examination of the discharges from cases of pyorrhœa alveolaris with the object of determining the presence of a specific micro-organism. He has been unable to find such an organism but has found that the organisms present possessed well-marked pyogenic properties. In the light of our present knowledge pyorrhœa alveolaris should perhaps be regarded as suppurative periodontitis. Pyorrhœa is an insidious and in many ways an intractable disease. If, however, it is recognised at the onset and properly treated it may be held in check and the teeth may be saved for many years. The signs of the disease are a soft, flabby condition of the gums which are also deeply congested and tender. The teeth are unduly moveable in their sockets, and on gently pressing the gums pus will be noticed to flow freely from around their necks. On closer examination it will be found that a fine probe can be passed some distance up the sockets of the teeth showing that the periodontal membrane has been stripped off. A deposit of tartar is nearly always present around the necks of the teeth. The treatment should consist in the removal of all hard deposits from the roots of the teeth. This should be followed by thorough irrigation of each tooth socket with some antiseptic and for this purpose peroxide of hydrogen (20 volumes) is excellent. The inflammatory condition of the gums must be treated with astringents. Local treatment carried out regularly on the lines indicated, with attention to the general condition of the patient, will produce a considerable improvement in most cases.

COAL SMOKE ABATEMENT: THE CLAIMS OF AN INVENTION.

THE smoke question has assumed such proportions that any mechanical arrangement for the suppression or abatement of the nuisance naturally commands attention. We are informed that Sir William Richmond, the President of the Smoke Abatement Society, accompanied by Mr. Arthur Ventriss, surveyor and engineer to the Strand District Board of Works, Mr. Edward Turner Atkinson, mechanical engineer to the London County Council, Mr. Samuel Goodall, of the Acton District Council, and other gentlemen, including several medical officers of health and a number of officers of the different sanitary authorities, met recently to inspect some machines supplied by Messrs. Ransomes and Rapier which were on view at the premises of Messrs. Taylor Bros., cocoa manufacturers, Brick-lane, E. The inspectors are said to have been satisfied that there was absolutely no visible smoke where the machine was employed, which sounds too good to be true. Mr. Churchill, one of the directors of Messrs. Taylor Bros., claimed that by the use of the machine increased economy and

efficiency to the extent of 25 per cent. resulted and that there was almost a complete immunity from wear and tear, the machines in two and a half years not having cost a penny in repairs, every part, bars included, being in as good condition as when first put in. The coal used was small Derbyshire, that previously used being best Welsh coal. Mr. Atkinson, who is admittedly an expert on this subject, having put a number of searching questions to the engineer in charge and made an exhaustive examination of the machine, expressed himself as perfectly satisfied, and was of opinion that an apparatus was now before the public which would not only enable steam-users to comply with the provisions of the Act for the prevention of smoke, but which it would actually be to their interest, both as regards saving in coal and extra boiler duty, to adopt at their works. We understand that these mechanical stokers are being extensively used both in London and the large manufacturing towns.

MEDICAL MEN AS CORONERS.

MR. F. W. LOWNDES, chief surgeon to the Liverpool police, has re-issued his pamphlet entitled, "Reasons why the Office of Coroner should be held by a Member of the Medical Profession." He gives his reasons clearly and we find ourselves in accord with his arguments, while we are naturally interested in his illustrations of the advantage of medical training to a coroner, seeing that he cites two inquests held before the late Thomas Wakley—the well-known Hounslow flogging case and the Hillingdon case of 1850—in the course of the latter of which investigations a further examination made at the coroner's suggestion of the throat of a man supposed to have died as the result of a fight disclosed a piece of meat which had lodged so as to choke him. Unless this further examination had been brought about before the body was buried an innocent man might have been committed to take his trial for manslaughter. It is contended by some that the coroner should be a trained lawyer, but it was the opinion of the late Mr. Wakley that enough law for the necessary purposes of the office could be acquired in a day, and we see no reason materially to modify this opinion; although, no doubt, a barrister of some standing, who has enjoyed a practice, may have had useful experience in dealing with witnesses and juries and in the understanding of statutes and decisions—so that the ideal coroner would no doubt be one trained both as a lawyer and a medical man. In support of the medical coroner Mr. Lowndes calls attention to the fact that the coroner's first duty—and a very important one—is to decide when a death is reported to him whether the cause of it is unknown or whether it has otherwise taken place in such circumstances that an inquest need be held. For arriving at a correct decision upon this point the best equipment must of necessity be a medical training; while, again, when the inquiry is being held the medical training of the coroner is essential if the viewing of the body by coroner and jury, obligatory by law, is not to be, as it often is, a meaningless formality. We are aware that the holding of an inquest may involve the committal for trial of a person supposed to be criminally responsible for the death inquired into. Persons are, however, very often committed for murder and manslaughter by magistrates of no legal education and less experience than a coroner should gain after a few months' work, while the cases in which such committals take place at the hands of the coroner form a smaller proportion of the number of inquests held than many suppose. According to the latest blue-book on the subject in 1898 inquests were held in England and Wales on 34,541 persons and only in 3210 cases was death found to be due to wilful or criminal acts, while of these 3210 cases 2881 were suicides. The remainder included 169 cases of murder, 145 cases of manslaughter, five cases of justifiable homicide, and 10 executions. Again, if any still think that the committal of a prisoner to take his trial for murder or manslaughter by a person not a lawyer may involve a danger to the public, we must point out that although a prisoner may in law be put upon his trial upon the coroner's inquisition only without further preliminary, he is always also examined before a magistrate or magistrates. Before the magistrate only such evidence may be given as is legally evidence against the accused, excluding much that may quite properly be relevant at the coroner's inquiry into the cause of death, and the magistrate may not think the evidence sufficient to justify a committal. Should the magistrate commit the prisoner for trial a bill of indictment is then sent before the grand jury at the next assize. Should the magistrate decline to commit, or should the grand jury throw out the bill, the prisoner is never, as far as we know, tried upon the coroner's inquisition alone, but by the judge's permission the Crown tenders no evidence and he is set at liberty. Those who consider the expense and trouble that may be caused and the amount of pain that may be given to bereaved relatives by the holding of an unnecessary inquest will be in accord with us in our view that a medical man is the right person to decide whether an inquest should be held or not. Those who calculate the amount of medical evidence which it must have been necessary to explain to juries in the course of inquests held in a single year on nearly 35,000 dead bodies will agree with us that, again, for the actual holding of the inquiry the medical training is more likely to be of use to the coroner than the legal training. His duties had once a wide range; they still are of great importance but are practically limited to inquiries into the cause of death, the few additional functions that might be mentioned not demanding any considerable legal knowledge.

THE DISSEMINATION OF PLAGUE BY RATS AND FLEAS.

PLAGUE has now been established in Sydney for several months, and in an address delivered before the New South Wales Branch of the British Medical Association on April 7th Dr. Frank Tidswell of Sydney discussed a variety of interesting questions relating to the disease. In reference to rats, he said that there were many instances which showed that the presence of a plague rat was responsible for the illness in man. For example, a number of dead rats found one morning in a cotton factory at Bombay were removed by 20 coolies. Within the three following days about half of them fell sick with plague, whilst those in the store who had not touched the rats were not affected. Again, the coachman of an English family in Bombay found a dead rat in the stable and removed it. Three days later he fell sick with plague and died in a few hours, no other person in the same house being affected. Many persons, however, have caught plague without handling plague rats and many persons have handled plague rats without catching plague. To explain this difficulty Simond[1] has suggested that the infection is carried by the fleas natural to the rats. Perfectly healthy rats harbour very few fleas and are very expert in removing them, but fleas are abundant on sick rats. After death, as the body becomes cold, the fleas leave it. In this way Simond accounted for the fact that a plague rat may be handled with impunity some hours after death. If the fleas from the dead rat reach another rat or a human being, they may inoculate the bacilli they acquired by ingesting the blood of their former host. In some of Simond's experi-

[1] Propagation de la Peste, Annales de l'Institut Pasteur, 1898.

ments sick and healthy rats in separate cages were enclosed in a glass jar and it was found that when no fleas were present the healthy animals did not become infected.

"CHRISTIAN SCIENCE" AT HOME AND ABROAD.

WE mentioned recently that a powerful body of Oddfellows in America has decided to decline as members all persons associated with the semi-religious body known as "Christian Scientists" on account of the high rate of mortality shown to prevail in a fraternity which declines to avail itself of the services of medical men in cases of illness. This seems to show that provident associations of the nature of Oddfellows have some appreciation of the practical value of their medical attendants, however little respect or generosity they may exhibit towards them. It also suggests that in the United States, where "Christian Science" has more followers than with us, life insurance companies will do well to take it into account in their policies, while even in London this society eccentricity may some day have to be reckoned with by such associations. In England considerable attention was not long ago attracted to "Christian Science" by the inquiries resulting from two deaths among its members, particularly from that which followed the death of Mr. Harold Frederic, the novelist, but the deliberate neglect of medical aid is usually associated in our minds with the prosecution of parents belonging to the sect known as the "Peculiar People." A husband and wife, for example, belonging to this last-named body were brought before Mr. Justice Bigham at Chelmsford in June owing to the death of a child who had died in spite of their obedience to the mandate of the 14th verse of the 5th chapter of the Epistle of St. James, and they were each fined £5. But the "Christian Scientists," appreciating the fact that the indulgence extended to fanatics of the uneducated class would hardly be extended to them, are, we believe, careful not to interfere with the treatment of children, at all events in cases which they believe to be dangerous. The perusal of an article by Mr. H. T. Marshall in the June number of the *Johns Hopkins Hospital Bulletin* (Baltimore, U.S.A.) shows the wide spread of "Christian Science" in the country of its origin, and so explains the necessity of the attitude adopted towards it by the Oddfellows referred to above. The writer, without suggesting what discount he would allow for the inflation natural to such figures, informs us that it is claimed that in the United States a million people have received "Christian Science" treatment, while its enrolled members are put at about half a million, which shows that the danger has there reached a point at which it must be taken seriously. Mr. Marshall proceeds to give an interesting criticism of the "religious" and philosophical dogmas propounded by Mrs. Mary Baker G. Eddy, the aged founder of "Christian Science," from the point of view of its bearing on "Christian Science" treatment, or rather neglect, of the sick, while he ends by pointing out the dangers to human life which may result and to suggest precautions by the community. Foremost among these he naturally places insistance upon the proper notification of births, deaths, and contagious diseases, for which of course there exists ample machinery with us—machinery which is put in motion without difficulty when occasion occurs. With us, however, the danger is not a serious one as in the States owing to the craze not having "caught on" to the same extent, while, as we have seen, the fear of prosecution has a restraining effect in the case of children. Besides which a little reliance on the good sense of the average Englishman and Englishwoman and a glance at the congregation as it files into the "Christian Science" services in London alike tend to reassure us. Among the phrases quoted by Mr. Marshall from the writings of Mrs. Eddy occur the following: "The daily ablutions of an infant are no more natural or necessary than would be the process of taking a fish out of water every day and covering it with dirt in order to make it thrive more vigorously thereafter in its native element." "When there are fewer doctors and less thought is given to sanitary subjects there will be better constitutions and less disease." The bearings of these observations, as Mr. Bunsby would have said, lie in the application of them, and applying them to the smartly dressed ladies who sing hymns to the accompaniment of a grand piano and are soothed by solemn rigmarole in the comfortably furnished room in Bryanston-street, which is the London centre of their body, we should say without hesitation that they have their babies "tubbed" and send for the plumber or mason when the soil-pipe gets blocked as if no such nonsense as "Christian Science" had ever been concocted to confuse their "mortal minds." To them such precautions are as "natural and necessary" as the toilette with which they adorn bodies that, according to their teacher, only exist in their diseased imaginations. Beyond this they are precisely the followers best suited for enrolment in a congregation which should consist of those blest with the variety of "matter" known to the uninitiated as money, and they are precisely the order of human being most likely to suffer from ailments that may be dealt with by mental suggestion, while they are the least likely to suffer from those more serious troubles for which mental suggestion hardly affords a palliative. "Christian Scientists," as Mr. Marshall tells us, undertake to cure every form of disease by inducing the patient to disbelieve in its existence and acquire faith in their God. When they venture to deal with a child too young to understand their jargon they proceed to "heal" him or her by convincing the parents that there is nothing the matter. Methods such as these are to some extent harmless where, in fact, nothing is the matter, and "cures" of apparently serious disease wrought in cases where mental suggestion might naturally be expected to be effective probably account for much of the faith undoubtedly established in many minds by "Christian Science" preachers and "healers." At the same time, danger may at any time arise in individual cases; for instance, it is obvious that a woman might well have it suggested to her a few days after childbirth that she was perfectly able to arise from her bed and go about her ordinary duties and pleasures, and might obey the suggestion with results beyond the power of "Christian Science" to persuade into non-existence. Still, considerable protection is afforded to children in this country, however silly their mothers may be, by the fear of criminal proceedings, while children and women alike find some protection in the authority of the male members of the family. Men are scarce in the "Christian Science" congregation, and fathers and husbands are apt to impose limits beyond which nonsense may not be carried in their households, although a humorous story was recently circulated of a gentleman who consulted a "Christian Scientist" healer owing to an accident having left one of his legs shorter than the other. The healer was charming and highly successful, but she unfortunately went abroad during the progress of the cure, being able to conduct it equally well at a distance, and when last seen her patient was despairingly hunting for her lost address, unable to warn her without it that the injured limb was not only restored to its proper length, but was already longer than the other and still growing.

HORSE AMBULANCE IN LONDON.

AFTER the appearance of the article in the *Nineteenth Century* by the Hon. Dudley Leigh on Horse Ambulance for London, Mr. S. Osborn, F.R.C.S., chief surgeon of the Metropolitan Corps of the St. John Ambulance Brigade, wrote an article, a copy of which is now before us, in which is embodied a scheme for a complete ambulance

system for London, a scheme which in no way entrenches upon the very excellent work which is so ably undertaken by the above-mentioned Corps. It is a subject upon which he is well able to advise and not long ago he advocated its claim for urgent consideration before a specially convened meeting at the House of Commons. Whether an ambulance system for London should be under the control of the St. John Ambulance Association, the Metropolitan Asylums Board, or the London County Council was fully gone into by him, and he was able to show that it was only through the London County Council that the scheme could be efficiently carried out. He has been in communication for some time with this body with this object in view—viz., of grafting an ambulance system for London on to the Metropolitan Fire Brigade, by whom it could be easily horsed, housed, and supplied by alarm calls. The scheme has received the support of several members of the Council and one influential member has lately promised to take the matter in hand.

MEDICAL INSPECTION v. QUARANTINE IN THE UNITED STATES.

OLD customs die hard, even in a country deeply imbued with the spirit of originality and progress, but nevertheless the principle involved in the English method of medical inspection of vessels is making a substantial advance in the United States of America. The State of New Jersey has recently passed a Bill framed to prevent the introduction into that State of communicable diseases by maritime vessels or maritime traffic; and although the local boards of health are by it invested with full powers of detention it is not difficult to detect between the lines that medical inspection, isolation, and disinfection are the principles which will govern the action of the State and local authorities. It is by a system of "permits" that infected vessels will be allowed to approach the ports of New Jersey. All infected vessels are to be "examined, cleansed, ventilated, and purified," and even vessels which have passed any quarantine station on Long Island or in New York Bay and obtained a written permit to proceed to New Jersey ports are not allowed to land their passengers or merchandise until such permit has been deposited with the local authority and another permit obtained. With regard to the prevention of yellow fever it is laid down by the regulations based upon the Acts referred to that from May 1st to Nov. 1st no person shall leave or go on board any vessel arriving from any port south of Cape Henlopen until a proper permit has been issued; and in respect of infectious diseases generally permits shall only be granted if the vessel be found free from the "infection of yellow fever, cholera, typhus fever, bubonic plague, small-pox, diphtheria, scarlet fever, measles, or other diseases of a contagious, infectious, or pestilential nature." Furthermore, it is not permissible to land straw or bedding from any vessel from any foreign port or place until it has been disinfected by exposure in a closed chamber to steam at not less than 240° F. for 30 minutes. It will be seen that in certain aspects these regulations go considerably beyond those in force in this country, and this is more particularly the case with respect to diseases other than cholera, yellow fever, and plague. As to small-pox, for instance, it is laid down that when any person arriving at any of the New Jersey ports has been exposed to the infection of this disease that person shall either be vaccinated or subjected to detention and isolation for a period not exceeding the incubation of the disease in question. This is a fair alternative, but it seems to us that some provision is necessary to meet the case of those who have been recently vaccinated. The prevention of small-pox infection by maritime channels is a most useful precaution, but in order that consistency may be maintained it is necessary that all trains and travellers passing into this State from outside should be similarly dealt with.

THE CARE OF THE FEEBLE-MINDED.

FEEBLE-MINDED persons are to be found at all ages in every social class; their numbers are considerable, as shown by the reports of the Departmental Committee of the Education Board concerning children and a committee of the Charity Organisation Society. Many of these persons die young, but they survive in sufficient proportion to form an appreciable element among the adult population. The condition of these persons is in many ways a matter of importance to the public as well as to their friends. The work of caring for the feeble-minded and trying to benefit their condition is difficult and expensive, but it is an imperative duty and may yield unexpected benefits in valuable knowledge gained as to grades of brain power and scientific methods of increasing its growth while aiding mental development and removing causes of brain disorder by adapted training. Experience has shown the need of more accurate means of diagnosis and description of this class of case, and the many and varied conditions found among such cases, as also of studying the best methods of training, stimulating, and controlling deficient brains. Feeble-minded persons not certifiable as imbeciles should not be classed as or associated with idiots and lunatics; in fact, their intercourse with those of sound mental powers is desirable when practicable. The Commissioners in Lunacy are not responsible for those cases under public control as not being certifiable under the Lunacy Acts. The recent Education Act, 1899 (Defective and Epileptic Children), constitutes the Education Board the authority responsible for the inspection of the schools and special classes for defective children and for the distribution of the Parliamentary grant. We have received a copy of a memorial of the National Association for Promoting the Welfare of the Feeble-minded addressed to the President of the Local Government Board, asking that steps may be taken to institute an inquiry into the number and constitution of feeble-minded persons in receipt of Poor-law relief. Such an inquiry, conducted by competent medical men on lines settled beforehand, is very desirable. An example will be found in the report on 100,000 children examined by Dr. Francis Warner for a committee of the Charity Organisation Society and the British Medical Association. A recent conference of Poor-law guardians resolved that it is expedient that homes for the permanent protection of the feeble-minded should be multiplied throughout the country. We heartily recommend the proposal and would add that in every such home means should be taken also to promote the mental development of the inmates as well as to supply industrial occupations. The Local Government Board have in contemplation, it is stated, the preparation of a Bill providing for the better classification of inmates of workhouses and for the removal of imbeciles and epileptics; it is very desirable that in any such re-arrangements provision should be made for persons who are "feeble-minded" but not certifiable as imbeciles or lunatics.

STREET NUISANCES.

IN our issue of July 7th, p. 39, we remarked that the police in the neighbourhood of the Strand, at any rate, did not seem to be taking advantage of the powers conferred by the new by-laws of the London County Council. We are glad to see, however, that on July 6th two newsvendors were summoned before Mr. Plowden at Marylebone Police-court for shouting. Their names were Foster and Blackman, but Foster did not appear. Blackman, in defence, said that

he knew of the by-law, but thought that it only applied when a private person made a complaint. Mr. Plowden is reported as saying that he hoped the by-law would receive the fullest attention from the police and that they would not hesitate to use their powers whenever the opportunity offered. It was a most salutary by-law and the offence was complete if a person shouted to the annoyance of anybody. Blackman would be fined 10*s*. We hope that Mr. Plowden's remarks will be laid to heart by the police, and especially by those of the C and E Divisions. Mr. Plowden is to be congratulated upon his change of opinions as to noises. His sympathy with the "natural noises of animal life"[1] evidently does not include the noise made by the "runner." We are glad to see, too, that on the same day a window cleaner was charged at the Guildhall with standing on a sill "more than six feet from the ground." This was the first case under the new by-law of the London County Council. The defendant pleaded ignorance of the law and was mercifully let off.

THE ATHLETIC MASTER IN SCHOOLS.

A SHORT article in the *Contemporary Review* for July by Mr. H. J. Spenser, LL.D., is somewhat severe on the athletic master in schools and equally so on the headmasters who rush to engage the man who has achieved a reputation for mere physical prowess. Dr. Spencer bases his remarks very much on the legend of a noted "Blue," who on completing his century in a recent 'varsity match received five telegrams from as many headmasters offering him posts. He admits that in the majority of cases the headmaster tries to secure first the intellectual and teaching qualities which are the chief requisites in all schoolmasters, but is evidently of opinion that the temptation is strong and often yielded to to appoint a man for his popularity among boys, which is always best secured by the performance of physical feats. Dr. Spenser thinks not only that the athletic master is not necessarily a good teacher—rather the reverse; but he charges him generally with slackness in intellectual work or in promoting such work in others, with being untidy and unsystematic, with never condescending to small details in life, with no sense of obligation, and with being a tax on the forbearance and forethought of others. As he advances in life "his nights are usually devoted to cards, his clothes reek of tobacco, and the necessity for physical fitness is no longer cogent." He does not command the respect of his pupils, though on the field he may excite their admiration. He conveys to boys an utterly false view of the respective importance of work and play. There is much truth in this view of a certain type of athletic master. But we do not think the type is very common and we are not disposed to allow that even any serious minority of headmasters would be so unfaithful to their highest duty—that of selecting their subordinate—as to prefer men of mere physical fitness to those of intellectual and teaching aptitude. Undoubtedly the wise headmaster will have an eye to recreation and play, and of two men seeking work in his school, other things being equal, he will prefer the man who has some sense of the pleasure of physical life and activity—and rightly so. What boys in school need is an object lesson of the *mens sana in corpore sano*.

RUSSIA AND THE PROBLEM OF INTEMPERANCE.

RUSSIA, like all other progressive countries, is feeling the necessity of facing the question of intemperance arising from the existence among its simple-minded and good-natured peasantry of innumerable dram-shops where alcohol of the lowest quality and coarsest description is served out to the poor. The diseases due to alcohol, including the loss of moral self-control, abound, and the people were bartering themselves as slaves to the dram-seller. We commend to the notice of our readers and to that of all who are contemplating temperance legislation in our own country the letter on this subject of our Special Correspondent at the Paris Exhibition which appeared in our issue of July 7th, p. 53. The Russian Government in 1894 commenced to take the sale of alcohol into its own hands. Mere dram-shops in many provinces have been abolished and no indemnity whatsoever has been paid to the dram-shop keepers. Profits made by the State from the sale of alcohol have been given to temperance committees to establish taverns or places of social intercourse, restaurants, reading-rooms, libraries, concert halls, lecture halls, and the like. It will be curious to watch the effects of this measure on the future of Russia. One great good will be the better nourishment of the peasantry, who will spend their money on sound food. A great decrease in drunkenness and crime is already reported.

[1] THE LANCET, Jan. 28th, 1899, p. 276.

THE NEW ISLINGTON INFIRMARY, HIGHGATE HILL.

AN event of some significance and interest is to be honoured with the presence of Royalty on the 16th inst. at 4.30 P.M. Their Royal Highnesses the Duke and Duchess of York have kindly agreed to attend the ceremony of the opening of the Highgate Hill Infirmary connected with the parish of St. Mary, Islington. The ground is somewhat classic. The infirmary is built on the site of the old Small-pox Hospital where Marson did his immortal work in the observation of small-pox and of the effect on it of vaccination. But the new institution has an importance of its own. It is meant for the sick of this large parish—the most populous in the kingdom. Unfortunately pauper sickness seems to grow even faster than the population and to require for its treatment something very different from the old workhouse accommodation for paupers. We shall probably give our readers some details of the new institution next week. Meantime it is noteworthy that the Duke and Duchess of York should graciously show their concern for the welfare of the sick poor by their presence at the opening ceremony.

THE HOUSING PROBLEM IN RURAL DISTRICTS.

PART III. of the Housing of the Working Classes Act, 1890, has not up to the present been made much use of in rural districts, and an inquiry which has recently been held by the Essex County Council into an application on the part of the Malden Rural District Council to adopt this part of the Act has brought out some interesting points. The proposal is to erect a dozen cottages at Bradwell-on-Sea, at which place there are 121 occupied cottages. Of these cottages 22 have one bedroom, 77 two bedrooms, and 22 three bedrooms; but of the total 121 only 18 are regarded by the local surveyors as being in good condition. The district council are proposing to erect 12 cottages at a cost of £2500, including the land, and the surveyor estimates that at a rental of 3*s*. a week an annual loss of £50 would fall upon the rates. The county council commissioners think, however, that this figure is below the mark and that £60 more correctly represents the truth. There seemed, indeed, to be a feeling at the inquiry that under no circumstances could a higher rent than 3*s*. a week be paid for the cottages, while others thought a rental of 1*s*. 6*d*. should suffice. The commissioners point out that this question of rental is obviously the crux of the position and that under the present system the cottages attached to farms are frequently let considerably below their proper rental. In this

connexion they relate the evidence of one of their witnesses to the effect that a certain land-owner built for the use of a farmer two cottages at a cost of some £400; the farmer pays rent at 4 per cent. on the outlay in addition to doing repairs and paying rates and taxes. The annual expenditure of the farmer on these cottages is about £22—i.e., about 4*s*. 6*d*. per week for each cottage—but the rent which he charges his labourers is but 1*s*. per week—i.e., the men's wages are 3*s*. 6*d*. in excess of the nominal figures. The commissioners condemn this indirect method of payment and urge that if the farmers would increase the men's wages and charge the full rent some inducement might be offered to private building enterprise. The application of the district council is, it appears, likely to be granted and the experiment will be watched with interest by all those anxious to bring about a better state of affairs in some of our rural districts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ANNUAL MEETING OF FELLOWS.

THE annual meeting of Fellows was summoned for Thursday, July 5th, at 5 P.M., but the election of members of Council delayed the entrance of the President, Sir William Mac Cormac, Bart., K.C.V.O., for about ten minutes. As, however, the number of Fellows required to form a quorum, 30, were not present, the President waited a quarter of an hour, and at the end of that time rose and declared that no meeting could take place as only 18 Fellows were present. He further pointed out that at the three previous meetings summoned no quorum had been obtained, so that the minutes of July, 1897, had not been yet confirmed. Until this year two meetings had been summoned yearly, but in 1899, in consequence of the repeated failures in getting a quorum, the Council had decided to call only one meeting each year. As it appeared that the Fellows were not sufficiently interested in these meetings to care to attend it might be possible that the Council would decide to do away with fixed meetings of Fellows and would themselves call a meeting when it appeared advisable, or on the requisition of a certain number of Fellows. We fear that the privilege of meetings of the Fellows, obtained after so much exertion, will shortly be withdrawn by the Council. The only agenda were three motions by Mr. R. B. Anderson.

Mr. H. Lockwood and Dr. A. H. Downes, Local Government Board inspectors, on July 10th opened an inquiry at St. Pancras Vestry Hall into the alleged irregularities which have recently taken place with regard to the certification and removal of lunatics.

SIR H. BLAKE, the Governor of Hong-Kong, in a telegram to Mr. Chamberlain received at the Colonial Office on July 9th, 1900, reports that 65 fresh cases of plague and 68 deaths occurred last week.

A CIVIL list pension of £50 has been granted to Mrs. Eliza Arlidge in consideration of the labours of her late husband, Dr. John Thomas Arlidge, in the cause of industrial hygiene, and of her straitened circumstances.

PRESENTATIONS TO MEDICAL MEN.—Mr. James C. M. Kinnear, M.B., C.M. Aberd., of Laurencekirk, Kincardineshire, on the occasion of his leaving the district, has been the recipient from his friends of a gold Albert chain and pendant.—Mr. T. Macdonald, M.B., C.M. Edin., has been presented with a centre-piece by the Highland Railway Ambulance Class, Inverness, in appreciation of his ambulance instructions.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

New Nationalities.—Scientific, Medical, and Surgical Exhibits of Hungary, Italy, and Switzerland.

ONE of the practical services rendered by Universal Exhibitions is that of revealing to civilisation the advent of new nations in its midst. Take, for instance, the Universal Exhibitions from the one held in Hyde Park in 1851 down to that apotheosis of the Second Empire, the first Universal Exhibition held in the Champs de Mars in 1867—up to that date there was no Hungary. Now, on the contrary, excepting the Trocadéro which is devoted exclusively to colonial exhibits, the horizontal tricolour of Hungary may be seen proudly displayed in all directions. Though now a thousand years have elapsed since Arpád and his mystic seven chiefs led the Magyars to the borders of the Tisza and the Danube, Hungary as a modern and independent nationality does not date back further than to the Austro-Hungarian compromise of 1867. But what giant strides have been made since that date, the nation accomplishing in each succeeding decade the work of a century. For instance, and as indicating the spread of intellectuality, there were but nine printing firms at Budapest in 1848, and 10 years after the re-establishment of the Constitution of 1867 there were 51 printing establishments in the capital and 198 in the provinces. To-day there are 660 printing firms in Hungary, of which 147 are at Budapest. Whereas in 1868 only 50 per cent. of the children went to school, now the school attendance is equal to 80 per cent. of the juvenile population. These primary schools to-day cost 38,182,306 crowns per annum, instead of 7,520,246 crowns, as in 1868. In the same interval the State subventions to schools have increased from 1,500,000 crowns to 10,000,000 crowns. For secondary education the cost has increased from 6,741,000 to 20,000,000 crowns and the number of pupils from 36,569 to 56,441. The University at Budapest had 96 professors in 1867 and 295 professors in 1899. In many other directions similar progress is to be noted and the result is manifest by the large share that Hungary has taken in the present Universal Exhibition. Naturally medical education has had its place in this general progress and development, and of the many public works undertaken some relate to water-supply, drainage, hospitals, clinics, university buildings, and other services bearing on the preservation of the health of the nation. Not least among these are the improvements in agriculture, as they tend to increase the food-supply and the cost of the necessities of life. All this is made manifest at the exhibition not only by the exhibits themselves but by numerous explanatory pamphlets and a special and semi-historical catalogue of the Hungarian exhibits published by the Royal Hungarian Commissariat.

The Hungarian section in the department of the Exhibition devoted to letters, arts, and sciences is compact and well organised; it is easily accessible, its situation being in the western wing of the main building on the Champ de Mars. Care has been taken to show that every encouragement is given to the study of the sciences, and the various Hungarian institutes created for this purpose have their exhibits. Thus the Hungarian Institute for the Study of Forensic Medicine, which is under the direction of Dr. B. Kenyeres, exhibits stereoscopic photographs of wounds and other injuries that were the subject of legal investigations. The Anatomical Institute of Topogr has a very fine display of bones, while the Botanic Institute, managed by Professor Istvanffy, has models of plants artistically prepared and some plants preserved in alcohol. Professor Leschner's clinique for mental diseases sends a cephalograph for mapping the convolutions of the brain in relation to the walls of the skull. Then there are the exhibits of the schools of anatomy and notably that of the Budapest Faculty of Medicine—sections of the pelvic region, the circulatory system, &c. But what strikes the eye first is a large collection of models of human teeth. These are from four to five inches in length and are most carefully painted, so that the appearances in caries and various other diseases are readily perceived by reason of the exaggerated size of the models. The teeth are held up by a brass frame and in the lower part, the leg or stem of the frame, there is space for the

introduction of a circular piece of paper about an inch and a half in diameter. In this medallion are drawings or enlarged photographs of the specific microbe associated with the disease which the model tooth above illustrates. There is likewise a large assortment of apparatus used in the schools of chemistry. The first group of apparatus deals with the classic demonstrations, the second with the analysis of gases, and the third with scientific researches, the last-named including spectroscopic analyses. A neat little pamphlet with good illustrations is given by the attendants to those visitors who seem to take a serious interest in the subject, and it contains full explanations.

Another pamphlet gives many details concerning the ophthalmological clinic of the Hungarian Royal University at Budapest. This clinic was founded in 1801, but it was then part of the surgical teaching and it was only in 1867 that its present active and separate existence began and that a chair of ophthalmology was created. Yet as far back as 1770 Professor Joseph Plenk delivered a separate course of lectures on ophthalmology at the University of Nagyszombat and in 1780 an annual grant of 200 florins was given so that such lectures might be continued. In 1801 the first ophthalmological clinic was created. It consisted of two rooms and six beds. One of the earliest teachers of ophthalmology at Budapest, Le Febure, Baron of Saint-Ildefont, won so great a reputation that he was appointed in 1790 by Louis XVI. as surgeon to the Court of France. He was the author also of some well-known works on the subject. In 1813 a law was enacted by which no one was allowed to call himself an oculist unless he possessed the diploma of doctor and surgeon and had obtained from the professor of ophthalmology a first-class certificate which was only given after two examinations, the first on theory and practice and the second on operations. The growth of this branch of surgery may best be realised by the following comparative figures. There were at the ophthalmic clinic of Budapest 507 out-patients and 87 in-patients during the year 1850. In 1898 there were 8983 out-patients and 983 in-patients. The record of operations does not seem to go further back than the year 1875, when 291 ophthalmic operations were performed; these increased to 1171 in 1898. Professor William Schulek, assisted by a numerous staff, is now the director of this clinic, which is located in the central block of the Faculty of Medicine. A plan is given of these extensive premises. The ground floor is devoted to the out-patients, the consulting and operating rooms, &c., and on the upper floor there are beds for 60 patients, isolation rooms for contagious cases, baths, &c. Thus a detailed idea of the hospital arrangements and the facilities for medical and surgical education which exist in Hungary can be obtained without going any further than the Paris Exhibition. Then there are also large diagrams prepared by Professor A. Hogyes setting forth what has been accomplished by the Pasteur Institute of Budapest. These include coloured maps of Hungary which indicate the prevalence of rabies in the different counties for many years. From this it appears that 9023 persons were bitten and suspected of rabic infection during the period 1890 to 1897. The cases of rabies that ensued numbered 283, or 3·13 per cent. of the persons who had been bitten. Of these persons 7528 were inoculated, of whom 117, or 1·55 per cent., had rabies. Of the 1495 persons who were not inoculated 166, or 11·10 per cent., had rabies. Of the 7528 persons who were inoculated 53 could not receive the proper or complete treatment: 22 fell ill while undergoing the course of inoculations, and 31 within 15 days of the last inoculation. Consequently it is claimed that though 7528 persons were treated, those who were treated in time numbered 7475. Of this latter number only 64 suffered from rabies and therefore the proportion of those who were fully and properly treated and who nevertheless were victims of the rabic poison amounted to only 0·85 per cent., instead of 1·55 per cent. Behind these statistics of the Hungarian Pasteur Institute are a number of oil-paintings representing the coats of the stomach during and after injections of cold water, of warm water, of mineral waters, and of water containing solutions of different acids or Karlsbad and other salts. These were taken with the Leiter-Mikulicz apparatus by Dr. Charles Morelli. There are also a few surgical instruments and orthopædic apparatus, &c., and then we come to the exhibits of the Hungarian crafts as taught in the technical schools.

Facing the Hungarian section in this department is that of Italy, a nation which is at once so old in history and yet so young as a modern and united kingdom. Here the visitor is constantly greeted by the characteristic sounds of music from guitar and mandolin, while a large photograph of the ruins of the Roman Forum and reproductions of the best Italian Old Masters give local colour to the section. On a broad table are piles of very artistic and cheap photographs of Italy, its ruins and its best paintings, so that the visitor may take away with him a suitable souvenir. But there is very little in this section of special technical interest. There are a few artificial teeth, a gymnasium, and some rough, cheap school furniture. Among the latter there are a desk and seat, which can not only be raised or lowered according to the size of the pupil, but the board on which the feet are placed can also be raised several inches. Thus the children may be lifted up all to the same height and a small boy would be able to see even though a big boy might be in front of him. Also the raising of the feet from the floor may be of use in case of dampness or draughts and thus the feet can be kept dry and warm. Close by Dr. C. Ghillini has an orthopædic measuring apparatus. In front there is a large pane of glass which is ruled in squares of a centimetre each. Behind the glass there is an upright nickel staff with moveable arms attached. One arm is placed above the head of the patient and measures his height; two arms hold each side of the head, whilst other arms press against the side of the body and their points reach the ruled glass in front. With their aid a life-size drawing or tracing can be made on the glass indicating the deviations rapidly and accurately. That was about all of a technical description which I noticed in this section. The exhibits of the Italian universities and the reports, drawings, &c., of public works bearing on public health are to be found in the gallery inside the Italian Palace in the Avenue of Nations.

Crossing the main passage again the exhibits of Switzerland are next to those of Hungary. Here also we find appropriate music, for there is a room surrounded with musical boxes which in turn play well-known and popular melodies, and it is not necessary to remark that the musical box is essentially a Swiss speciality. In the next compartment is another but a much better and more elaborate collection of school furniture. The desks, being larger, suggest plenty of elbow-room, and they enable the visitor to realise that the Swiss in respect to primary education have set an example to all Europe. Then there is a delightful room, with a comfortable velvet settee in the centre, where the weary investigator finds a welcome resting-place while he contemplates the surrounding gorgeous array of coloured photographs of Swiss alpine scenery. Here, too, there is a big table where all that Switzerland gives us in the form of photographic souvenirs can be cheaply purchased. Having rested in this cool, shaded compartment, which to the exhausted visitor will appear as a real oasis, he will find outside enlarged photographs of the human fœtus compared with that of a chicken. They are hung on a partition that is in a somewhat obscure corner and away from the general traffic. There is also the fœtus of a snake as compared with that of a chicken and some very remarkable and minute skeletons of the human fœtus which have been preserved by Dr. Eternod of the Geneva University. Close at hand Professor Emile Young exhibits beautiful specimens to demonstrate the morphology of anthropodes and the visceral anatomy of vertebrates. Then Messrs. Reymond Frères of Geneva have a large assortment of dental chairs, furniture, &c., and apparatus for making plates, casts, and other things connected with artificial teeth. M. J. Heinz of Bâle has an extensive exhibit. The first compartment represents an operating room. The operating table is of nickel, in three moveable parts, and is drained by a central groove. The instrument case or cupboard is of glass and metal; one side of the door fits into a groove on the other side and at the bottom of the groove there is a soft material which on being pressed tightly prevents any ingress of dust. Some of the tables are of porcelain on metal legs, but the porcelain, though beautifully smooth and bright on the upper surface, is rough and unpolished underneath, so that dust can adhere just where it is least likely to be seen. There is an apparatus that looks like the back or head of an iron bedstead; its two legs are on wheels. This can be affixed to the ends of a bed that is not on castors. By a lever arrangement the bed can be raised an inch or two from the floor, and then it rests on the wheels of the apparatus and

can be rolled along without disturbing the patients. Thus if there is a hospital where none of the beds have castors or wheels a couple of these contrivances will in a moment supply temporary wheels to any bed which it is necessary to move. But perhaps the most interesting exhibit is a sectional drawing illustrating the ventilation of an operating-room. Here a large space under the floor is devoted to this purpose. First, there is an air filter, then a fan propellor. After these there are a compartment for heating the air, a pulverised spray for moistening, and, finally, the shaft for delivery into the operating-room. Thus the amount and the quality of the air supplied can be regulated and does not depend upon the accident of outside meteorological conditions. Facing these objects Messrs. Fr. Klingelfuss and Co. of Bâle show electric apparatus used in dental surgery and for the examination of the throat, the nose, and the ears, as well as for cauterising, &c.

Messrs. Knœbel and Laubscher, also of Bâle, exhibit a large assortment of surgical instruments manufactured in Switzerland and some bronze aluminium thread for sutures which has attracted some attention. Next to these are the very interesting exhibits of bandages, &c., manufactured by M. H. Russenberger, of Geneva. The absorbent or hydrophile cotton-wool shown here raises important technical questions that merit careful attention on the part of operating surgeons. As a rule, this cotton-wool is made with the cotton-waste purchased from the mills. If such cotton were properly purified there would be no harm in its employment, but it not unfrequently contains as much as 5 per cent. of chemical waste products from the mills. For surgical purposes the safest plan is to employ, as in this case, virgin cotton imported direct from America. Apart from its greater purity it is not injured by manipulation, therefore the fibres are stronger and of greater length. Also there is a larger volume for equal weight and it is more elastic. A band made of virgin cotton-wool does not break so readily and therefore it is easier to dress a wound. A band of cotton-wool of this description is shown. It is some four feet in length and one and a half inches wide. Suspended by one end from the top of the case or stall it has, at the other end, a weight of one kilogramme; yet unless violently shaken it will not break. But the chief object is a rapid and large absorption. Formerly this property was tested by placing a little of the wool on the surface of a basin of water and watching how long it would take before it became immersed. M. Russenberger proceeds in a more conclusive manner. He takes a test-tube and places some coloured liquid at the bottom and then fills up the tube with the cotton. The height to which the coloured liquid travels and its penetration into the centre of the cotton show in a more certain manner the absorbent qualities of the latter. By these means is effectively demonstrated the superiority of virgin cotton to that of the waste cotton from the mills. Another point is the use of boric acid in cotton-wool dressings. Lord Lister has said that there should be from 50 to 60 per cent. of acid, but cotton-wool thus impregnated cakes and is difficult to use. This is due to the fact that the wool is soaked in a hot solution of the acid. Consequently a great deal of wool sold only contains 10 per cent. of boric acid. In the present instance the wool is impregnated by sprinkling the acid in a powdered condition and then passing steam through. But even by these means a sufficient quantity cannot be mixed with the wool unless it be by a cumulative process. Therefore the operation is repeated several times, and thus at last a cotton-wool bandage is obtained that contains 50 per cent. of its own weight of boric acid. So, also, instead of using glycerine to fix antiseptic powders on bandages, this is likewise done by a process of pulverisation. Glycerine is not always a suitable substance and, for instance, it will turn airol red when exposed to light. Then there is the question of sterilising wool, bandages, &c. What is the good of this precaution if after sterilisation the substance treated is to be brought into contact with the atmosphere, touched by the hand, and packed up in parcels? The bandages, &c., here exhibited are not thus exposed, but are first packed in parchment and then sterilised by steam under pressure. After a time the steam is turned off and nothing is touched till all is quite dry. The articles are then put into a second envelope and must not be opened till they are required for use. So that the operator may be satisfied that the sterilisation has been complete a small tube containing the loose powder of phthallic acid is placed in the centre of the packet. If this powder, instead of being loose, is found adhering to the side of the tube this proves that it has been exposed to a heat of 129° centigrade. Such are some of the technicalities of the scientific preparation of bandages, &c., as exhibited in the Swiss section. Before leaving this section I should not omit to mention a portable operating table devised by Professor Auguste Reverdin of Geneva especially for the use of rural practitioners. It weighs in all 15 kilogrammes. The legs are of hollow cycle tubing and fit into each other in a telescopic manner. The whole can be neatly packed and carried like a portmanteau. There is also another non-portable table consisting of three hollow parts that can be filled with warm water to prevent the patient suffering from cold. After examining these technicalities the visitor will perhaps be pleased to terminate his inspection and to rest himself by contemplating large plaster-cast models of the Swiss Alps.

Paris, July 9th.

THE WAR IN SOUTH AFRICA.

FROM a military point of view there has not lately been much to record. The enemy's troops can scarcely be regarded now as really organised forces and the fighting has assumed the type of guerilla warfare. The telegrams from South Africa show that the campaign is slowly but surely drawing to a close. The Boers are evacuating strong positions to take up others, and that alert and clever tactician, De Wet, still manages to slip out of our grasp with his troops. It is singular how seldom we seem to take any large number of Boers as prisoners or capture their guns. What has become of their artillery?

There is a widespread prevalence of enteric fever among our troops in South Africa. This fever is the scourge of all modern warfare and we are afraid it will continue to be so. Although typhoid fever is classified as a preventable disease it is uncommonly hard to prevent it under all the conditions of war. The more rapidly a campaign can be conducted the better for everyone, but the harder it is on all sanitary, transport, and supply departments. The mortality statistics of enteric fever in South Africa compare favourably on the whole with those of other wars or of India. A reference, too, to the statistics of the London Fever Hospital and to those of the Metropolitan Asylums Board will show that the percentage mortality at the army ages of soldiers is in excess of the average for all ages and this has, of course, to be borne in mind.

If the campaign in South Africa has from a purely military standpoint reached a dull stage of late as compared with the earlier and more exciting periods of its history this cannot be said of its medical aspects, for we are living in the clash of contentions and contradictory statements. About one thing, however, there can be no doubt, and that is that while there is an overwhelming amount of enteric fever at certain places the disease seems to be more or less prevalent everywhere in South Africa at the present time. It would be comparatively easy to deal with it if it were only known beforehand where the incidence of sudden and severe outbreaks was likely to occur, which is just what cannot be done. South Africa as a whole is of some 442,000 square miles in extent, and although the theatre of war has not this area it nevertheless occupies a very large one and the available means of communication are very limited for the great number of troops in the field. There was not long ago an epidemic of typhoid fever at Maidstone and to provide the requisite number of suitable hospitals and trained nurses for it was by no means an easy task, notwithstanding that Maidstone is not far from London by rail. How much more difficult must it be to do so in the case of epidemic outbreaks on a large scale in Africa, for they must be trained nurses to be of any good in the case of typhoid fever patients; untrained attendants, however well disposed, would be more likely to prove an encumbrance than otherwise. Where are all these trained nurses to be had? However, a commission will soon be constituted and sent out to South Africa to inquire into the sickness and medical arrangements there. We can quite appreciate the force of Lord Roberts's request that some of its members should be persons of strong common sense.

The last issued official return of the War Office shows the total casualties since the beginning of the war up to the end of last week, but exclusive of sick and wounded men in

British hospitals in South Africa, to be 30,693. The list is made up as follows:—

—	Officers.	Non-commissioned officers and men.
Killed in action	255	2,411
Died from wounds	70	625
Missing and prisoners (excluding those who have been recovered)	59	1,927
Prisoners died in captivity	1	84
Died from disease	137	4,398
Accidental deaths	—	68
Sent home as invalids	916	19,742
Total	1438	29,255

(FROM OUR SPECIAL CORRESPONDENT LATELY AT THE BASE.)

Bloemfontein and enteric fever are synonymous at present, though I am glad to say we are gradually getting the best of it; it has, however, been a hard fight and many have gone down in the contest. When I tell you that besides the three big general hospitals, Nos. 8, 9, and 10, which have been accommodating any number between 1000 and 1500, there are the Langman, the Irish, the Portman, the Radzali, and the Volkes Hospitals, all more or less full up, it will give your readers some slight idea of the work of the medical staff during this campaign. Few people will realise unless it is explained to them, that each of our big general hospitals is treating at present nearly double the number of patients that can be accommodated at University Hospital or St. Mary's Hospital, and when the thousand and one other duties that are absolutely necessary are taken into account, such as rations, supplies, conservancy, and the internal economy of the various units of the Royal Army Medical Corps, St. John Ambulance, and the Cape Medical Staff Corps, to say nothing of the vast army of regimental orderlies who are doing duty in place of our own men who are ill or invalided, I think it will be acknowledged that life out here at present is not all rose coloured. The climate is excellent—cold and frosty in the mornings and evenings and comfortably warm during the day; and were everything else equal it ought to be an ideal spot for invalids and convalescents.

When I left Cape Town the only general hospitals left were Nos. 1 and 5, all the others having gone up country, and by the time you get this I hope our own may be also at Pretoria or Johannesburg. Of course, the number of surgical cases are now few and far between, but I expect the engagements that have beeen taking place round Pretoria will mean that we shall soon be having some more sent down. The great convalescent camps that exist here, at Norvals Pont, and at Springfontein are a great boon and enable men who, though seedy, are by no means so ill as to require to be sent to England, to pick up and rejoin after a brief stay. Two more new hospital trains, admirably fitted and equipped, have been added to the existing number and are performing excellent work, and besides these we have most comfortable saloon trains running at brief intervals for convalescent patients who do not require lying-down accommodation or special diet and nursing. Our number of nursing sisters is being augmented daily, and I cannot say too much for the way these ladies have been working under circumstances which, owing to the exigencies of warfare, must have been often disheartening in the extreme. Everyone speaks well of their devoted work, and no praise is too much from us who see them day after day and night after night going on steadily and earnestly in their labour of unselfish devotion to their duties.

As I predicted in my earlier letters disease has claimed far more victims than the Mauser bullets, and anyone who at the commencement of the war would have predicted that our sick would reach a total of over 10,000 would have been a true prophet, though he might at that stage of the proceedings have been discredited. As regards the enteric fever it is very difficult to say at present to what source it can be traced. It is undoubtedly endemic in Bloemfontein, which is not to be wondered at when one comes to look a little into the sanitary arrangements of the town, which are practically *nil*. The majority of our cases were transferred from the various field and stationary hospitals which seem to have brought them from the Modder and Paardeberg, where the disease was contracted during the stay of the troops in these localities. One of the worst features about this disease is that it absolutely unfits men for further duty for at least three months—which, of course, means that they must be sent home, the voyage being one of the main factors in the convalescent treatment which all these cases require. At present the line is blocked between this place and Kroonstad owing to the Boers having cut the communication, and several of the hospital trains and members of the staffs of the hospitals which are up at the front are temporarily detained here. Luckily there is plenty of excellent accommodation in the way of hospitals at both Pretoria and Johannesburg so that no inconvenience will be felt, and long ere you receive this the line will have been cleared. I shall not enter into any statistics regarding the enteric fever as you will doubtless have more extended reports than I have time to give you, but I can confidently state that the mortality does not exceed the average—in fact, when one comes to analyse the returns they certainly furnish a subject for congratulation as far as the mortality is concerned.

Bloemfontein, June 16th.

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

We have had a terribly sad week since last I wrote to you owing to the death of two young officers, each of whom, though their ways lay far apart, had endeared themselves to many members of our camp. Early in the week came the bare statement, and even yet we have heard no details at all, of the death in action of Lady Chesham's son. Only a few weeks ago he passed through here on his way to the front for the first and last time and everybody who met him was won by his cheery good spirits and good heart. On the day we heard the sad news our chaplain held a memorial service, for a gloom was cast over the whole of our camp. But it was only the forerunner of another event the sadness of which came even more home to the staff and patients of this hospital, for in the death last Friday, June 15th, of Dr. R. T. Fitz-Hugh everybody here felt that they had lost a friend whose value they had had the opportunity of realising. He was one of the juniors among our medical officers, but his practice here among the patients had cemented the high opinions which had been formed at Guy's Hospital by his teachers no less than by his contemporaries from his earliest student days and which had been fortified by the high degrees he had taken at the London University. He was popular alike with his colleagues, with the nursing sisters, with the non-commissioned officers and orderlies, and with the patients. His career gave every promise of his attaining a very high place in his profession; but apart from his value to this hospital in his professional capacity he had many characteristics which had endeared him to those who knew him. He was a thorough sportsman, a prominent member of our cricket eleven, though perhaps best of all at Association football, in both of which sports he used to play for Guy's Hospital when he was a student. He was a man with a keen sense of humour and quite the most popular performer at the smoking concerts which do so much to keep up the spirits of our camp. One song of his in particular was so popular that however much he tried to satisfy the audience with others they never would let him leave the piano until he had given them their favourite Poor old "Fitz," as we always called him, will not quickly be forgotten by his friends. There was an enormous congregation at his funeral service, the first part of which was held in the church. All ranks of the hospital were largely represented and formed into a long procession to follow him to the cemetery about a quarter of a mile away. The coffin was carried by orderlies, and four of his fellow Guy's men acted as pall-bearers.

On the day that he died the entire staff was kept busy by the arrival of two trains full of sick and wounded, the first day on which we have ever experienced such a heavy "take in." The first train load was the earliest out of Mafeking. Poor fellows, they are thin! But you will hardly need me to tell you this, nor that they are plucky. I was much struck by the coolness displayed by one of the officers. He was shot

through the leg, and a few yards further on through the chest. That brought him down, but the Boers put two more bullets into him at forty yards' range while he was on the ground. He thought the best thing to do to save further damage was to sham dead. They came and looted his pockets and he found it very difficult to maintain the sham. Later he was taken into the Boer laager as one of the wounded, and the first thing he did was to protest against having been looted before he was dead! But this he did so eloquently that the Boer in command had his watch searched for and returned to him. Professor J. Chiene of Edinburgh came down with this train. The second train arrived from Wynberg and Senekal, and out of 96 occupants there were no fewer than 50 "stretcher" cases—i.e., patients so gravely ill that they had to be carried from the train to their beds. Many of the wounded from the latter neighbourhood presented a feature which was entirely novel to our experience in that they were burned more or less severely. It seems that our troops had had to advance through veldt fires. A few of them were burned in running through; others only got their burns when they fell to the ground wounded, but from the accounts of the survivors I fear that there must have been others again still less fortunate who, when they fell to the ground, were unable to move and were burnt to death. No. 3 hospital train, which brought the latter load, left again immediately for Mafeking, and Colonel Sloggett went up in it with the intention of bringing down all the rest of the sick and wounded from that place. Still lying there is a cousin of mine, Major Mullins, of the Imperial Light Horse, who, after being wounded through the shoulder at Elandslaagte early in the war and then being locked up in Ladysmith throughout the siege and having enteric fever in Intombi camp, formed one of the relief force and had the bad luck to get wounded in the back just before they got into Mafeking. Professor Chiene, who saw him in Mafeking, tells me that both legs were completely paralysed at first, but that now there is so much improvement as to warrant the hope that he may regain the use of both. I sincerely hope that Colonel Sloggett will find him and all the others still left in Mafeking—some 50 we were told—well enough to travel, in which case we shall have the pleasure of putting the splendid resources of this hospital at the service of all those who were laid up in Mafeking or wounded in its relief.

The blowing up of the railway north of Kroonstad has not really affected our material interests here at all, for most fortunately all three hospital trains (for a third one has just been improvised out of the ordinary saloon carriages with a kitchen truck in the middle) were south of that part at the time, and therefore their regular running has not been interfered with.

Professor Chiene was originally coming out as senior surgeon to the 100-bed Scottish Hospital recently established at Norval's Pont, but the day before he left home he was appointed a consulting surgeon to the Forces by the War Office in one of the vacancies created by the home-going of Sir William Mac Cormac and Mr. Treves. He stopped the whole day with us and I took him all round the hospital. He made a most minute inspection of everything and carried away, for the benefit of the Scottish Hospital to which he was going, a sample of any little device that struck him as novel. He was much fascinated, for instance, by the way buckets are improvised here out of empty oil cans. He and the two other medical men and the two sisters on the Mafeking train lunched and dined with us and he left again late at night, having expressed himself extremely pleased with everything he saw. The operating theatre, the laundry, the disinfectant house, and the latrines were the parts he admired most of all.

We have had to turn one of the smallest huts into a sick room for the sisters. They are so closely packed in the ordinary sisters' sleeping huts that it is extremely inconvenient there when one of them is ill. I am glad to say that there are no serious cases amongst them, but their work is very heavy now, and their sick room is in perpetual request for slight cases. Greenfield and Parker, the other two medical men who I told you had enteric fever, are both doing well. Three others of our medical staff have had to be admitted to the officers' ward during the past week, but we do not think that any of them have enteric fever. Exactly a quarter of the orderlies we brought with us are now sick in hospital. In spite of this attenuation of our staff we are still expanding our accommodation and have now 800 beds, although nearly a hundred of them are not occupied, 50 being reserved for our expected load from Mafeking, and from 30 to 40 we always keep vacant, as I have told you before, for chance arrivals.

Deelfontein, June 18th.

IMPERIAL YEOMANRY BRANCH HOSPITAL.

(FROM A CORRESPONDENT.)

Before Mr. Burdett-Coutts's letter had appeared in the *Times* Lord Roberts telegraphed to London from Pretoria that he would like another Yeomanry hospital sent out if possible.

The committee, with their usual promptness, despatched four days after the receipt of the telegram the nucleus of the medical and nursing staff of a new hospital destined for Pretoria or Johannesburg or any other spot decided on by Lord Roberts. The remainder of the staff were under orders to leave Southampton a week later. The first departures consisted of F. M. Sandwith, M.D., F.R.C.P., who is taking a summer holiday from Cairo; W. Langdon Brown, M.B., assistant physician to the Metropolitan Hospital and casualty physician to St. Bartholomew's Hospital; H. Williamson, M.B., B.C., late house surgeon at St. Bartholomew's Hospital; and S. F. Crowther Smith, M.B., late house physician at St. Bartholomew's Hospital. The matron is Miss Nisbet of the East Dulwich Infirmary, who earned her first laurels at the Chalcis Hospital during the late Greek war. She left in charge of 11 nurses of the Royal Army Nursing Reserve, and the staff were accompanied by 81 orderlies, many of whom have had previous nursing experience. Most of the equipment will be provided on arrival at the Cape. The party is also accompanied by Colonel Lucas and Colonel Deane who are proceeding to South Africa to report upon the various Yeomanry units now serving at the war. The Yeomen already number over 11,000.

JENNER INSTITUTE OF PREVENTIVE MEDICINE.

THE annual general meeting of the Jenner Institute of Preventive Medicine was held at Chelsea on June 29th, Lord LISTER, the President, being in the chair. Amongst those present were Sir Joseph Fayrer, Surgeon-General Hooper, Professor Greenfield, Professor W. G. R. Simpson, Dr. McCrury, Dr. Bridgwater, Colonel Addison, and Mr. S. G. Shattock.

The governing body reported that during the year the work of the Institute had continued to afford valuable results. The transference of Lord Iveagh's gift for the promotion of the objects for which the Institute was founded had been effected and the governing body which would in future control the affairs of the Institute had been constituted. Reference was made to the loss the Institute had sustained through the death of His Grace the Duke of Westminster.—The report of the TREASURER (Sir Henry Roscoe) was read and adopted.

The report of the DIRECTOR (Dr. Allan Macfadyen) stated that during the year the Institute's work had continued to progress. The following paragraphs are taken from the report: "The fitting up of the Chelsea building, which has occupied a good deal of my time during the past three years, is now completed with the exception of the museum. The foundations and footings on the vacant portion of the building site have been laid down, and this will facilitate building operations in the event of its being decided to proceed with the erection of the new wing. Amongst new features added during the year may be mentioned (1) a physiological room, (2) a room for incubating purposes, (3) a laundry, (4) a workshop, and (5) a cold-storage-room.

"Mr. Briggs has presented to the Institute a Hansen apparatus for yeast-culture and considerable additions have been made to the library. The first laboratory meeting of the Pathological Society of London was held at the Institute. During the year I visited the laboratories of Professors Behring and Ehrlich and those of Meister, Lucius and Brüning at Höchst. A second volume of the Institute's Transactions has been published. The volume contains 19 contributions and includes a paper

by Professor Ehrlich. Professor Welch of the Johns Hopkins University writes: 'I congratulate you upon the excellence of the scientific work recorded. Every paper is a genuine contribution of real value. The Institute is a splendid success and all English-speaking physicians have reason to be proud of it.'

"Three papers have been communicated to the Royal Society upon the influence of the temperature of liquid air and hydrogen upon bacterial life. The experiments were conducted with the kind coöperation of Professor Dewar and a further series is contemplated upon life at low temperatures. In conjunction with Dr. Morris and Dr. Rowland a paper has been submitted to the Royal Society on Expressed Yeast-cell Plasma (Buchner's 'Zymase'), a subject of considerable biological interest. The research has been the means of giving us a new method for triturating organisms. Systematic investigations are being carried out in the bacteriological department upon enteric fever, tuberculosis, and the etiology of cancer, with the coöperation of Dr. R. T. Hewlett and Dr. Rowland. Various investigations have been published during the year by Dr. Hewlett and other members of the staff. It is proposed to set on foot a systematic inquiry into the nature and origin of food poisons.

"A number of workers have utilised the laboratories for purposes of research during the year. Special investigations were carried out for public authorities during the year—e.g., upon tubercle in milk, glanders, anthrax, &c. The illustrations for the Transactions were prepared by Mr. J. E. Barnard in the photographic department of the Institute. Mr. A. Harden, chemist to the Institute, reports that he is continuing his investigations upon the chemical products of pathogenic and other micro-organisms. Dr. G. Harris Morris, lecturer on technical mycology, states that a number of students have utilised the facilities of the Hansen Laboratory, whilst researches upon yeasts, diastases, zymase, and other subjects of technical interest have been prosecuted. Dr. George Dean, in his report of the work of the antitoxin department, states: 'In connexion with diphtheria antitoxin many experiments have been made with the view of ascertaining the best conditions for obtaining powerful toxins and antitoxins and in testing the results claimed for the methods of other workers. The improvement in the strength of the toxins and in the method of immunising the animals has resulted in a higher average of antitoxic value being reached, so that the increased demand for this antitoxin has been successfully met. Several races of streptococcus pyogenes have been used in immunising horses with the view of obtaining a polyvalent serum. The War Office and several of the consulting surgeons who have gone to South Africa have been supplied with the tetanus and other antitoxins. Researches dealing with problems of immunity are in progress and papers have been published from the department upon the diphtheria bacillus and a new pathogenic streptothrix.'"

THE THIRTEENTH INTERNATIONAL MEDICAL CONGRESS, PARIS, AUGUST, 1900.

THE following arrangements have been made for British members who wish to attend the Congress to be held at Paris from August 2nd to August 9th. The South-Eastern and the Chatham and Dover Railway Company will issue tickets to members and their wives, but not to their families, on presentation of their cards of membership at the reduced rate for return tickets of 58*s*. 4*d*. first-class and 37*s*. 6*d*. second-class *viâ* Dover and Calais or Folkestone and Boulogne, available for 14 days; by the 2.45 P.M. service from Charing-cross or Cannon-street *viâ* Folkestone and Boulogne, and by the 9 P.M. service from Charing-cross, Victoria, Cannon-street, and Holborn *viâ* Dover and Calais. Each ticket will entitle the holder to a free allowance of 56 lb. of luggage and will be available to return from the Gare du Nord at Paris by the 3.30 P.M. or the 9 P.M. services. Those who wish to return by the 9 A.M. service *viâ* Calais and Dover, or the 10.30 A.M. service *viâ* Boulogne, may do so on payment of 7*s*. 1*d*. first-class and 3*s*. 9*d*. second-class on board the steamers. The special tickets will be issued every day from July 21st to August 10th and will thus be available for those who wish to attend the Congress of Medical Ethics, the Congress of the Medical Press, the General Medical Congress, and the Congress of Hygiene.

The London, Brighton, and South Coast Railway Company will issue on application to the Continental Traffic Manager, London Bridge Terminus, a day or two in advance of departure, 14-day excursion tickets available from London or any station on the Brighton Railway to Paris at 39*s*. 3*d*. first-class or 30*s*. 3*d*. second-class to members of the Congress. The tickets can be made available for the day service and the availability can be extended to, say, 25 days if desired. These tickets allow a break of journey at Brighton or Lewes, Newhaven, Dieppe, and Rouen, both in going and in returning. Members who apply for these tickets are required to give proof of their membership and should make their cheques payable to the London, Brighton, and South Coast Railway Company, addressed to Mr. T. N. Wylie, the Continental Traffic Manager at the London Bridge Terminus.

The London and North-Western Railway Company state that parties of 30 or more passengers travelling to Paris this season from a station outside the radius of 20 miles from London (the party travelling together on the outward journey, but individually if desired on the homeward journey) will be charged the single fare and a quarter for the double journey from the North of England to London and back, *plus* the 14 days' excursion fares from London to Paris in force by the different routes beyond London. The tickets will be available for 16 days—i.e., 14 days between London and Paris and two days extra between London and the provincial station.

The Midland Railway Company are prepared to make a similar concession for parties of 30 and upwards travelling together from stations over 20 miles from London.

The International Sleeping Car Company, 14, Cockspur-street, Charing-cross, London, S.W., are the agents for the Trocadéro Hotels in Paris. These hotels are situated on the Quai de Passy and the Boulevard Delessert, immediately adjoining the Trocadéro section of the Exhibition. They consist of four separate blocks, and being constructed solely of stone are so designed that when the Exhibition is over they may be used as flats. The position they occupy is in many ways unique, and their immediate proximity to the Exhibition grounds renders them most convenient for visitors to the Exhibition, and this, on account of the excessive charges made by the Parisian "cochers" for cabs, is a consideration. The hotels are pleasantly situated, two of the four blocks being on a level with the Quai de Passy, whilst the other two are on a level with the Boulevard Delessert, separated from the lower ones by a large garden and a series of terraces with fountains. The second floor of the two upper buildings is about on a level with the fourth floor of the two lower ones, so that the view over the Seine and over the whole of the Exhibition is the same from every part of the hotels. At present visitors are able to obtain bedrooms with one bed at from nine to 16 francs and double bedrooms at from 15 to 28 francs per day, including lights and attendance. The tariff for visitors *en pension* varies between 16 and 23 francs per head a day according to the floor and the aspect of the room occupied. These prices include bedroom, electric light, attendance, breakfast, luncheon, and dinner with wine, or beer, or mineral water, or milk. Early application, however, is now necessary and should be made direct to the Manager of the Sleeping Car Company, 14, Cockspur-street, S.W.

At Paris special rooms will be set apart on and after Monday, July 30th, for the use of the national committees of each country which may be used as a rendezvous for each nationality. These rooms will be in the buildings of the Faculté de Médecine. A postal telegraph office will also be opened at the Faculté de Médecine where members will find their letters and telegrams if they are addressed as under:—"Dr. ————, Member of the Thirteenth International Congress of Medicine, Paris."

STATE OF THE MORTUARIES AT DEVONPORT.—At an inquest held at Devonport on July 2nd the coroner described the Pottery Quay mortuary as a scandal and considered it his duty as coroner of Devonport to point out the disgraceful condition of things with regard to the mortuaries of the town. He added that the feelings of those who had had relatives placed there must have been very harrowing.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund up to noon on Wednesday last, when the total was over £40,000 :—

MEDICAL OFFICERS OF THE HIGHLANDS AND ISLANDS OF SCOTLAND.

THE following memorial has been signed by 40 medical officers:—

Unto the Honourable the Local Government Board of Scotland, the Memorial of Medical Officers of the more remote Parishes of the Highlands and Islands of Scotland humbly sheweth—

I.—That the Medical Officers of the more remote parishes of the Highlands and Islands of Scotland are required to perform their duties by night as well as by day, and on Sundays as well as week days, and in all states of weather.

II.—That the areas of practice of many of these Medical Officers are of great extent, so that it is no uncommon occurrence for the Medical Officer to have to travel from 10 to 30 miles to see a pauper patient; that consequently his travelling expenses are heavy, and that, moreover, he is sometimes unable to return home the same night.

III.—That the work is very trying to the health of the Medical Officer, especially in winter time; yet, as matters stand, he may not leave his parish for a holiday rest unless he provides at his own expense a duly qualified and registered Medical Practitioner as his substitute.

IV.—That the salaries of the Medical Officers are small, and that the population of the districts is scattered and very poor, so that few Medical Officers can earn more than from £20 to £50 a year beyond their official parochial salary; and that consequently the expense of providing a qualified medical substitute during a reasonable holiday is out of all proportion to the emoluments attached to the office.

V.—That all other Parish Officers may have the privilege of an annual holiday without having to place a substitute in their place at their own expense; the Parish Medical Officer alone being compelled to provide such a substitute at his own expense.

VI.—That many of these Medical Officers are compelled to reside far from railway or other convenient communication with the South, so that in most cases two or three days are necessary to travel to Edinburgh or other centres of population, and that the expenses of living in such isolated districts are great and the social amenities few.

VII.—That the Local Government Board of Ireland requires that a Board of Guardians shall give its Medical Officer an annual holiday and pay a reasonable fee to a qualified substitute, and that most of these Boards have cheerfully acquiesced in this requirement.

VIII.—We, the undersigned Medical Officers, submit that, as is the rule in similar districts and under similar circumstances in Ireland, we also should be granted the privilege of an annual holiday, and that the Parish Council should pay a reasonable fee to a substitute; that if one month were allowed—deducting a week for going and returning—the Medical Officer would have a clear three weeks' holiday, and that the expense to the ratepayers would be trifling.

IX.—And the undersigned Parish Medical Officers earnestly pray that the Local Government Board of Scotland will be pleased to look into the difficulties and disadvantages, in the respects herein set out, under which their Medical Officers in the outlying districts at present labour, and will take the whole position of facts mentioned in this Memorial into consideration and grant the prayer thereof.

And your Memorialists will ever pray.

In connexion with the above the following has been presented "Unto the Honourable the Local Government Board of Scotland."

We, the undersigned Members of Imperial Parliament, and others, desire to express our sympathy with the Memorial presented by the "Medical Officers of the more remote Parishes of the Highlands and Islands of Scotland," and our hope that your Honourable Board may see its way to accede to the prayer of their Memorial:—

This memorial has been signed by the following gentlemen, viz.:—Lord Lister, Sir William Arrol, M.P., Mr. J. E. B. Baillie, M.P., Mr. Augustine Birrell, Q.C., M.P., Sir Charles Cameron, Bart., M.D., M.P., the Right Hon. J. A. Campbell, M.P., Dr. G. B. Clark, M.P., Mr. J. Colville, M.P., Mr. J. W. Crombie, M.P., Mr. Alexander Cross, M.P., Mr. J. H. Dalziel, M.P., Dr. Charles Douglas, M.P., Sir William Dunn, Bart., M.P., Dr. R. Farquharson, M.P., Sir Walter Foster, M.D., M.P., Mr. T. C. H. Hedderwick, M.P., Sir J. G. S. Kinloch, Bart., M.P., Sir John Leng, M.P., Mr. James McKillop, M.P., Mr. Donald N. Nicol, M.P., Sir George A. Pilkington, M.P., Mr. A. Robinson Souttar, M.P., Mr. H. J. Tennant, M.P., Sir W. Thorburn, M.P., Sir John Batty Tuke, M.D., M.P., Mr. Alex. Ure, Q.C., M.P., Mr. Eugene Wason, M.P., Sir W. Wedderburn, Bart., M.P., Dr. William Bruce, LL.D. (Direct Representative for Scotland on the General Medical Council), Dr. James Dunsmure (President of the Royal College of Surgeons of Edinburgh), Dr. James Andrew (President of the Royal College of Physicians of Edinburgh), Sir Hector Clare Cameron, M.D. (President of the Faculty of Physicians and Surgeons of Glasgow), Dr. T. McCall Anderson (Professor of Clinical Medicine and Dean of the Medical Faculty, University of Glasgow), Professor R. W. Reid, M.D., F.R.C.S. (Dean of the Medical Faculty of the University of Aberdeen), and Professor E. Waymouth Reid, F.R.S. (Dean of the Medical Faculty of the University of St. Andrews). Of the Faculty of Medicine of the University of Edinburgh: Professor Thomas Annandale, F.R.C.S.; Professor William S. Greenfield, M.D.; Professor Henry D. Littlejohn, M.D., LL.D.; Professor C. Hunter Stewart, M.B., D.Sc.; Professor Alex. Russell Simpson, M.D.; Sir William Turner, M.B., D.C.L., LL.D.; and Professor John Wyllie, M.D., F.R.C.P., LL.D.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6553 births and 3220 deaths were registered during the week ending July 7th. The annual rate of mortality in these towns, which had been 14·9 and 15·1 per 1000 in the two preceding weeks, fell last week to 14·5. In London the rate was 13·5 per 1000, while it averaged 15·1 in the 32 provincial towns. The lowest death-rates in these towns were 9·1 in West Ham, 9·9 in Croydon, 10·1 in Bristol, and 10·2 in Birkenhead; the highest rates were 18·9 in Salford, 19·3 in Manchester, 19·9 in Liverpool, and 24·1 in Sunderland. The 3220 deaths in these towns included 344 which were referred to the principal zymotic diseases, against 366 and 419 in the two preceding weeks; of these 89 resulted from whooping-cough, 84 from measles, 63 from diarrhœa, 53 from diphtheria, 27 from scarlet fever, 26 from "fever" and two from small-pox. The lowest death-rates from these diseases were recorded in Croydon, in Birkenhead, and in Bolton; and the highest in Derby, in Sunderland, and in Swansea. The greatest mortality from measles occurred in Oldham and in Derby; from whooping-cough in Sunderland and Wolverhampton; and from diarrhœa in Gateshead. The 53 deaths from diphtheria included 20 in London, four in Swansea, four in Liverpool, and four in Leeds. Two fatal cases of small-pox were registered in Liverpool, but not one in any other of the 33 towns. There were 17 cases of small-pox under treatment in the Metropolitan Asylums Hospitals, on Saturday last, July 7th, against 15, 13, and 16 at the end of the three preceding weeks; four new cases were admitted during the week, against eight, none, and eight in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital at the end of the week was 1843, against numbers increasing from 1754 to 1810 on the four preceding Saturdays; 229 new cases were admitted during the week, against 210, 219, and 210 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 181 and 180 in the two preceding weeks, further fell last week to 140, and were 48 below the corrected average. The causes of 46, or 1·6 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, in Nottingham, in Cardiff and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool and in Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·5 and 17·9 in the two preceding weeks, fell again to 17·7 during the week ending July 7th, but was 3·2 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 8·4 in Perth and 9·3 in Paisley to 20·2 in Dundee and 20·3 in Glasgow. The 546 deaths in these towns included 32 which were referred to diarrhœa, 22 to whooping-cough, 20 to measles, four to scarlet fever, three to "fever," two to diphtheria, and two to small-pox. In all 85 deaths resulted from these principal zymotic diseases, against 60 and 83 in the two preceding weeks. These 85 deaths were equal to an annual rate of 2·8 per 1000, which was 1·3 above the mean rate last week from the same diseases in the 33 large English towns. The 22 fatal cases of whooping-cough showed a decrease of four from the number in the preceding week and included 17 in Glasgow. The deaths referred to measles, which had been 14 and 18 in the two preceding weeks, further rose last week to 20 and included 13 in Glasgow and three in Edinburgh. The fatal cases of diarrhœa, which had increased from 19 to 24 in the two preceding weeks, further rose last week to 32 and included 16 in Glasgow, five in Edinburgh, four in Dundee, four in Aberdeen, and three in Leith. The deaths referred to scarlet

* Including 12 cases of membranous croup.

† Including deaths from membranous croup.

fever, which had been two and seven in the two preceding weeks, fell last week to four, and included three in Glasgow. The three deaths from fever and the two from small-pox occurred in Glasgow. The two deaths from diphtheria included one in Edinburgh and one in Greenock. The deaths from diseases of the respiratory organs in these towns, which had been 87 and 97 in the two preceding weeks, fell last week to 72, but were 15 above the number in the corresponding period of last year. The causes of 31, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·9 and 20·0 per 1000 in the two preceding weeks, fell again to 17·8 during the week ending July 7th. During the four weeks ending on Saturday last the death-rate in the city averaged 19·9 the rate during the same period having been 14·7 in London and 17·3 in Edinburgh. The 119 deaths registered in Dublin during the week under notice showed a decline of 15 from the number in the preceding week, and included six which were referred to the principal zymotic diseases, against four and three in the two preceding weeks; of these, three resulted from whooping-cough, two from diarrhœa, one from fever, and not one from small-pox, measles, scarlet fever, or diphtheria. These six deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 1·5 in London and 1·7 in Edinburgh. The fatal cases of whooping-cough, which had risen from one to two in the two preceding weeks, further rose to three last week, and the two deaths from diarrhœa showed an increase of one. The 119 deaths in Dublin last week included 22 of infants under one year of age and 26 of persons aged upwards of 60 years; the deaths of infants were about equal to the average, but those of elderly persons were below those recorded in recent weeks. Seven inquest cases and six deaths from violence were registered; and 45, or rather more than one-third of the deaths occurred in public institutions. The causes of six, or 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1900.

IN the accompanying table will be found complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·9 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 6·6, 6·2, and 7·2 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, St. George Hanover-square, St. Giles, St. Martin-in-the-Fields, and Woolwich; while they showed the largest excess in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, St. Olave Southwark, and Lee sanitary areas. 23 small-pox cases were notified during June, of which six belonged to St. George-in-the-East, five to Paddington, five to Kensington, and three to Fulham sanitary areas; 20 small-pox patients were admitted into the Metropolitan Asylums Hospitals during June, and 16 remained under treatment at the end of the month. The prevalence of scarlet fever showed a further increase upon that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in Hackney, Whitechapel, St. George-in-the-East, Limehouse, St. George Southwark, and St. Olave Southwark. The Metropolitan Asylums Hospitals contained 1788 scarlet fever patients at the end of June, against 1654, 1619, and 1735, at the end of the three preceding months; the weekly admissions averaged 202, against 162, 174, and 198 in the three preceding months. The prevalence of diphtheria showed a slight decline from that in the preceding month; the proportional prevalence of this disease was greatest in Shoreditch, Bethnal Green, Limehouse, Newington, Lee, and Plumstead sanitary areas. There were 1212 diphtheria patients in the Metropolitan Asylums Hospitals at the end of June, against 1236, 1131, and 1402 at the end of the three preceding months; the weekly admissions averaged 151, against 148, 135, and 172 in the three preceding months. The prevalence of enteric fever showed a further decrease from that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in St. Pancras, Stoke Newington, St. Giles, St. Martin-in-the-Fields, Clerkenwell, and Lee. The Metropolitan Asylums Hospitals contained 148 enteric fever patients at the end of June, against 263, 208, and 176 at the end of the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Marylebone, Bethnal Green, Whitechapel, St. George-in-the-East, and Mile End Old Town sanitary areas. The 12 cases of puerperal fever included two in St. Pancras and two in Woolwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the sanitary areas in which the patients had previously resided. During the four weeks ending June 30th the deaths of 5201 persons belonging to London were registered, equal to an annual rate of 14·8 per 1000, against 19·1, 20·2, and 16·6 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 7·5 in Hampstead, 9·6 in Lee, 10·2 in Lewisham, 11·5 in St. James Westminster, and 11·7 in St. George Hanover-square, in Hackney, and in Wandsworth; the highest rates were 22·0 in St. Martin-in-the-Fields, 22·4 in Strand, 24·6 in St. Saviour Southwark, 25·6 in St. Luke, 27·7 in Holborn, and 29·4 in Limehouse. During the four weeks of June 616 deaths were referred to the principal zymotic diseases in London; of these, 217 resulted from measles, 37 from scarlet fever, 101 from diphtheria, 174 from whooping-cough, 30 from enteric fever, two from simple continued fever, and 55 from diarrhœa. These 616 deaths were equal to an annual rate of 1·7 per 1000, against 1·8 in each of the two preceding months. No death from any of these diseases occurred last month in St. Martin-in-the-Fields; in the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, St. James Westminster, Hampstead, St. Saviour Southwark, Lambeth, and Camberwell; and the highest rates in Paddington, Holborn, Clerkenwell, Shoreditch, and Limehouse. The 217 deaths from measles were 81 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Paddington, Holborn, Clerkenwell, Limehouse, Mile End Old Town, and Plumstead sanitary areas. The 37 fatal cases of scarlet fever showed a decline of 29 from the corrected average number; the greatest proportional fatality from this disease occurred in Fulham, Clerkenwell, City of London, Shoreditch, Limehouse, and St. George Southwark sanitary areas. The 101 deaths from diphtheria were 47 below the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Shoreditch, Bethnal Green, Newington, Bermondsey, Rotherhithe, and Lambeth. The 174 fatal cases of whooping-cough were three in excess of the corrected average number; this disease showed the highest proportional fatality in Stoke Newington, Holborn, Clerkenwell, Limehouse, St. George Southwark, and Bermondsey sanitary areas. The 32 deaths referred to "fever" were slightly below the number in the corresponding periods of the ten preceding years; among the various sanitary areas the "fever" death-rate was highest in Westminster, St. Pancras, Stoke Newington, Strand, Holborn, and Bermondsey sanitary areas. The 55 fatal cases of diarrhœa were only one-third of the corrected average number; the greatest proportional fatality from this disease was recorded in Chelsea, Stoke Newington, Holborn, St. Luke, Limehouse, and Lewisham sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during June was 30 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 117 per 1000. The lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Hampstead, St. Martin-in-the-Fields, Lewisham, and Lee; and the highest rates in Hammersmith, Strand, Holborn, Limehouse, Poplar, and St. George Southwark sanitary areas.

THE SERVICES.

MR. BURDETT-COUTTS'S CHARGES.

THE terms of reference of the proposed commission which is to proceed to South Africa are as follows:—"To report on the arrangements for the care and treatment of the sick and wounded during the South African Campaign."

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified: — Staff-Surgeons: J. H. Thomas to the *Camperdown*, lent, and A. M. Page to the *Australia*.

ROYAL ARMY MEDICAL CORPS.

The under-mentioned surgeons-on-probation to be lieutenants: Patrick Hagart Henderson, John Patrick Joseph Murphy, Arthur Rowland Greenwood, Frederick Hallam Hardy, William Moreland Haladay Spiller, Archibald Douglas Jameson, William Bennett, Bernard Bruce Burke, Walter Burgess Fry, Charles Richard Louis Ronayne, George Baillie, Llewellyn Lancelot Græme Thorpe, John Blake Hall, William Silvister Crosthwait, Percy Clarence Douglass, Richard Francis Ellery, Robert Lionel Popham, The following among them have arrived at Salisbury Plain and have been posted in the district as follows: Perham Down—B. B. Burke, to charge of stationary hospital; C. R. Ronayne, to charge of 3rd Brigade and duty in hospital; and W. B. Fry, stationary hospital and medical charge of details in Tidworth House. Bulford Camp—F. H. Hardy, to charge of stationary hospital; G. Baillie and G. Douglass, for duty in stationary hospital; and J. B. Hall, to charge of 2nd Brigade. West Down Camp—W. S. Crosthwait, to charge of details.

MILITIA MEDICAL STAFF.

Surgeon-Lieutenant-Colonel D. Jacob, 4th Battalion the Prince of Wales's Leinster Regiment (Royal Canadians), retires under paragraph 81 Militia Regulations, with permission to retain his rank and to wear the uniform of the battalion on retirement.

VOLUNTEER CORPS.

Artillery: 4th Durham (Western Division, Royal Garrison Artillery): William Gray to be Surgeon-Lieutenant. 1st Forfarshire: James Gray to be Surgeon-Lieutenant. 1st Glamorganshire: Surgeon-Lieutenant D. A. Davies to be Surgeon-Captain. 1st Shropshire and Staffordshire: Surgeon-Captain J. P. Massingham to be Surgeon-Major. The undermentioned gentlemen to be Surgeon-Lieutenants:—George Higginson and Wheelton Hind. 2nd Gloucestershire (the Bristol): Lieutenant T. H. Board to be Captain and Marcus John Eustace to be Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the King's (Liverpool Regiment): Lieutenant Henry D'Arnim Blumberg resigns his commission and is appointed Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF.

The London Companies: Surgeon-Lieutenant W. S. Sharpe to be Surgeon-Captain. The Woolwich Companies: Alfred Hugh Minton to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

The following have left for service in South Africa:—Civil Surgeons Owen, Davies, Ffrench, and Hunter.

The following have arrived in England from South Africa:—Major Kelly, R.A.M.C., Lieutenant Nicholls, R.A.M.C., Lieutenant Irvine, R.A.M.C., Major Whaite, R.A.M.C., Captain Dalton, R.A.M.C., Lieutenant Cuddon-Fletcher, R.A.M.C., and Civil Surgeons Nicol, Goodman, Thomas, and Stamford.

Major Nichol, R.A.M.C., is reported from Cape Town discharged from hospital to duty.

The following steamers have arrived at Southampton, bringing the sick and wounded men as detailed from the seat of war in South Africa:—The *Maine*, on July 4th, with 16 very severe cases; the *Avoca*, on July 5th, with 50 cases; the *Assaye*, on July 7th, with 693 sick and wounded; and the *Princess of Wales*, on July 9th, with 170 patients. On Tuesday afternoon, July 10th, H.R.H. the Duchess of York visited the Royal Victoria Hospital and was conducted over the surgical and medical divisions by Colonel Charlton (principal medical officer) and his staff. In the medical division Lieutenant-Colonel W. E. Webb, and in the surgical division Major C. Birt, explained the nature of the cases.

Six medical men and a number of nurses and ward maids have left for South Africa in the *Dunvegan Castle*. They form part of the remainder of the staff of the Imperial Yeomanry Hospital now being formed at Pretoria. The complete medical staff will be as follows:—Dr. W. Langdon Brown and Dr. Herbert Williamson, St. Bartholomew's Hospital; Dr. F. M. Sandwith, Kasr el Aini Hospital, Cairo; Dr. Stanley F. Crowther Smith, Mr. A. R. J. Douglas, and Mr. Howell Davies, St. Bartholomew's Hospital; Dr. F. Brickwell and Mr. F. L. Provis, Tottenham Hospital; and Mr. A. H. Hayes and Mr. C. S. Frost. Major Reade, R.A.M.C., is the commandant.

Of the 1009 invalid soldiers who have arrived at Plymouth during the past two months from South Africa only 120 now remain at the Military Hospital, Devonport. The majority of these are convalescent and will be shortly sent on sick furlough.

TRANSVAAL WAR CASUALTIES.

Surgeon-Lieutenant-Colonel James Creagh, 9th Battalion King's Royal Rifle Corps (North Cork Militia), died from enteric fever on July 6th, between Viljoen's Drift and Kroonstad.

THE RISING IN ASHANTI.

A telegram received from Mr. Low (Gold Coast) by the Colonial Office, dated Akwabosu, July 1st, says: "Crossed Ofin river June 30th and July 1st. Following Europeans left Kumassi with force. ..... Medical Officers Garland, Chalmers, Tweedy, Graham, Gold Coast Colony, (and) Macfarlane of Lagos. ..... Passage across Ofin river very difficult owing to floods. Hardships of journey from Kumassi have been very severe. Most of the severely wounded Hausas have since died; others are missing. In addition to officers mentioned in previous telegram as left in charge of fort add name of Hay, medical officer.—HODGSON."

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on July 10th, Sir J. N. Dick, K.C.B., late Director-General, R.N., being in the chair, the sum of £55 was distributed among the several applicants.

VOLUNTEER MEDICAL ASSOCIATION.

The annual meeting of the Volunteer Medical Association will be held at 20, Hanover-square, on Tuesday, July 24th, at 4.30 P.M. The council will meet at 4 P.M. Surgeon-Major John J. de Zouche Marshall, 3rd Volunteer Battalion the East Surrey Regiment, has been elected to the post of honorary secretary, vice Surgeon-Captain F. J. Warwick, V.M.S.C.

Deputy Surgeon-General Henry Cayley (retired), Indian Medical Service, has been appointed Honorary Surgeon to the Queen, vice Surgeon-Major A. Grant (retired), Indian Medical Service, deceased.

At Windsor Castle on July 7th the following Companions of the Order of the Bath were introduced into the presence of the Sovereign, and Her Majesty the Queen was graciously pleased to affix to their respective left breasts the Decoration of the Military Division of the Third Class of the Order: Colonel William Egerton Saunders, Royal Army Medical Corps; Surgeon-General Henry Skey Muir, Deputy Director-General Army Medical Service; and Surgeon-Lieutenant-Colonel Benjamin Bloomfield Connolly, A.M.S.

Correspondence.

"Audi alteram partem."

"THE LECTURERS AND LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND FROM 1810 TO 1900."

To the Editors of THE LANCET.

SIRS,—Your kind and appreciative notice in an annotation in THE LANCET of June 30th (p. 1894) of my "List of Lecturers and Lectures at the Royal College of Surgeons of England, 1810–1900," encourages me to ask you to be so good

MUSEUM LECTURES.

COMPARATIVE ANATOMY.

Date of delivery.	Name of lecturer.	Number of lectures.	Title of lecture.
1814	Astley Paston Cooper.	15	Comparative Anatomy.
1815	Astley Paston Cooper.	15	Comparative Anatomy.
1816	William Lawrence.	15	An Introduction to Comparative Anatomy and Physiology.
1822	Everard Home.	15	Comparative Anatomy.
1829	Herbert Mayo.	15	Anatomy and Physiology of the Nervous System in the Different Classes of Animals. Development of the Brain in Man and Functions of the Cerebral Nerves.
1830	Herbert Mayo.	15	Anatomy and Physiology of the Organs of Sense in the Different Classes of Animals. Physiology of Sleep, Volition, Muscular Action, Respiration, and Vocal Organs.
1832	Charles Bell.	15	On Life and Organisation; on the Skeleton; and on the Physiology of the Nervous System.
1833	Charles Bell.	15	On the Prospective Design indicated by the Adaptation of the Organs of Support, or the Hard Parts, of the Different Classes of Animals to their Habits, and to the Circumstances in which they are Placed. The Teeth in the Different Classes of Animals, and the Different Kinds of Articulation of the Bones, and the Arrangement of the Muscles similarly considered. Physiology of the Nervous System as connected with the Anatomy of Expression.

SURGERY.

1819	James Wilson.	9	Lectures on the Blood and on the Anatomy, Physiology, and Surgical Pathology of the Vascular System of the Human Body.*
1820	James Wilson.	9	Lectures on the Structure and Physiology of the Parts composing the Skeleton and on the Diseases of the Bones and Joints of the Human Body, preceded by some Observations on the Influence of the Brain and Nerves.
1821	James Wilson.	9	Lectures on the Structure and Physiology of the Male Urinary and Genital Organs of the Human Body and on the Nature and Treatment of their Diseases.†
1829	George James Guthrie.	9	Anatomy of the Circulating System in Man: History of its Development and Comparison of the Different Stages with the Permanent Structures in Inferior Animals. Functions of the Heart and Arteries and Veins. Injuries and Diseases of the Vascular System in Man and the Treatment of the Same.
1830	George James Guthrie.	9	On the Anatomy of the Human Pelvis: its Sexual and National Varieties; Comparison of it with the Pelvis in other Animals. On the Anatomy of the Human Urinary and Sexual Organs, illustrated by Observations of the Same Parts in the Inferior Classes of Animals. On Wounds and Injuries of the Head and Chest. On the Diseases of the Urinary and Sexual Organs, and more especially of Diseases of the Urethra.
1831	George James Guthrie.	3	On the Anatomy of the Parts concerned in Hernia.‡
1832	George James Guthrie.	9	Anatomy of the Organ of Vision in Man, illustrated by Observations on its Structure in the Lower Animals. On the Diseases of the Eye and its Appendages and the Treatment of the Same.
1833	Henry Earle.	9	On the Minute Anatomy and Physiology of the Urinary Organs. On the Diseases of the Same and their Treatment. On the Anatomy of the Colon, and the Nature and Treatment of Some of the Diseases of that Intestine.§

* Wilson completed this course in his Arris and Gale Lectures of this year.

† Wilson, who died in this year, had arranged for a further course on "The Brain and Nervous System."

‡ This course of lectures proceeded amidst much disturbance until the fourth lecture, when they were wholly interrupted by a systematic and continued riot. The lectures were consequently suspended and the theatre closed by the advice of the law officers of the College and by the concurrence of the trustees of the Museum until the sanction of the Chancellor and judges had been obtained to a by law enabling the President and Council to repress any similar disturbances in future.

§ Earle continued this course in the Arris and Gale Lectures of the same year.

is to give publicity to the accompanying amplifications and corrections of my pamphlet. Many of them I owe to Mr. D'Arcy Power; upon others I have chanced in a research into the history of the College. As the "list" is given away, not sold, to anyone interested in medical history it is not likely that it will see a second edition.

I am, Sirs, yours faithfully,

VICTOR G. PLARR,
Librarian of the College.

The Library, Royal College of Surgeons of England, July 2nd, 1900.

THE SOUTH AFRICAN COMMISSION.

To the Editors of THE LANCET.

SIRS,—As in the Crimea and in Egypt, so now in South Africa, war on a large scale seems to have as its invariable sequel accusations of neglect of sick and wounded involving mainly the Army Medical Department as responsible for the results, the conclusions of committees being hitherto impotent in the prevention of repetition of charges or of the conditions complained of. Another inquiry is in progress and it is a matter of profound importance to the accused department (for this is clearly the position of the Royal Army Medical Corps) that the proposed Commission should be so constituted as to contain within itself the means of eliciting the truth and the whole truth, and the requisite capacity to recognise and gauge the real import of the evidence; and from the facts adduced to fix the responsibility for shortcomings on the right shoulders and make proposals likely to prevent a recurrence in the future. Now, Sirs, when we note the tone of some of the debates in the House of Commons, the vacillation of the Government and the views expressed in the lay journals, I venture to think that to anyone bearing in mind the experience of the past and cognisant of army life, the duties of the Royal Army Medical Corps and the conditions under which its work has to be done in peace and in war, a feeling of grave scepticism will arise as to whether this Commission as proposed will be any more fruitful in results than its predecessors.

The original scope of the Commission as formulated by the Government was "to report as to the arrangements for the care and treatment of the sick and wounded during the campaign in South Africa" and to inquire especially into the complaints of negligence in regard to enteric fever; and to this end the Commission was constituted of three members—one judge and two medical men. And in view of the fact that the subjects embraced by it are mainly professional, requiring not merely "common sense," but a specially trained technical sense for their solution, the commission was one fairly capable of doing the duty entrusted to it. Mr. Balfour spoke of it as having "great qualities of knowledge and impartiality stamped upon it," and the Leader of the Opposition considered the medical members are "high-minded, straightforward men who will do their work well." Yet what do we find but the Government departing from their scheme, to which we must assume they had given reasonable thought, and agreeing to add two more members, neither of whom can have the necessary knowledge to guide them in such a professional inquiry, the numerical deciding power being now in the hands of those untrained to gauge the true import of the evidence and facts adduced! Moreover, the main objection to the original commission apparently was "that the inquiry would practically be in the hands of medical men," the view being held by some that medical men could not be relied on to act fairly in matters in which their fellow professionals were concerned, they presumably being deficient in that sense of justice and rectitude of purpose allowed to most men; and these are points which the profession would do well to lay to heart.

Further it would appear that the inquiry is to be extended to transport, &c. In the words of the leading Conservative journal, "the whole question of hospital administration at the seat of war and the general organisation and methods of the Royal Army Medical Corps will be thoroughly examined." And when cognisance is taken of this expansion the doubt still more is increased as to whether the Commission as proposed has the necessary capacity for the duties with which it is charged. In addition to what has been aforesaid, who among its members have that experience of war and that practical knowledge of the rules and regulations of the Service and the nature and work of the Royal Army Medical Corps and the conditions under which it is done as will entitle them to speak with authority on the matters to be inquired into?

Mr. Balfour himself expressed the possibility of the danger of unfairness to the army medical officers from the medical members owing to the former "carrying out their duties under conditions not very familiar to doctors and surgeons at home"—a danger augmented with a majority with everything to learn. And when we note the remarks of Mr. Burdett-Coutts *apropos* of himself we further recognise the possibility of injustice accruing either to the Department or to individual members. He is recorded to have said that in his grave indictment of the medical arrangements in South Africa he was originally in a position of a plaintiff, but now in that of a defendant of the great interest involved in the truth or untruth of his statement; and, going on to say that now the Government would call him as a witness to enable him to state his case with possibly the opportunity of producing other witnesses, he asks: "Was that enough in this case? What was the usual practice when a man was placed in his position? Had he not a right to put what questions he liked, to cross-examine the witnesses?"—questions which elicited cheers. Now it is apparent that the Department is the true defendant in this inquiry, and its position is exactly that which Mr. Burdett-Coutts details as characterising himself; and if these essentials to justice are requisite in the one instance why not in the other? Can it for a moment be said that the proposed Commission will contain within itself these essentials? What might go far towards placing it in a position to do for the Department what it cannot do for itself would be to add to it one or two independent army medical officers whose knowledge and experience would tend towards eliciting the whole truth and giving proper weight and importance to the facts adduced.

Well, Sirs, I take it for granted that the view of the Department is that neither in the Crimean nor in the Egyptian inquiry was justice meted out to it, and the possibility of a like fate befalling it in this instance has to be faced; not, of course, from set purpose, but from inability on the part of a Commission as proposed to decide on technical points and disentangle and rightly apportion its true responsibility among the more powerful army sections (including, of course, the War Office) which are also involved in this important and difficult inquiry. What does the country really want—a "scapegoat" for the relief of its feelings with a lapse into the old ways, as formerly, as soon as the excitement of war has passed away? Or is it for once thoroughly determined that the experience and teaching of the past shall not be lost, but shall bear such fruit as to make a recurrence of such departmental complaints an impossibility in the future? Have we solid grounds for such a hope?

I am, Sirs, yours faithfully,

FRANCIS H. WELCH, F.R.C.S. Eng.,
Surgeon-Colonel (retired), A.M.S.

Brandram-road, Lee, S.E., July 9th, 1900.

"THE CAUSE OF CARIES OF THE TEETH."

To the Editors of THE LANCET.

SIRS,—Dr. J. Sim Wallace holds that the great prevalence of dental caries among civilised peoples is due to their eating soft and pappy foods requiring little mastication. Some years ago you were good enough to publish in THE LANCET a letter from me in which I urged the same view. My interest in the subject led me to read Dr. Wallace's work carefully directly it appeared, and I hope I may be permitted to say that I was greatly impressed by the closeness of his arguments and the scientific spirit pervading his book.

My original contention was that soft foods predispose to caries by leading to imperfect mastication and thus to defective nutrition and development of the teeth; and although I still venture to think that this may be a factor Dr. Wallace has converted me to his view that soft foods lead to caries essentially by modifying the buccal environment of the teeth—the teeth being no longer properly cleansed by coarse fibrous foods, the buccal secretions being no longer adequately excited, and so forth.

Regarding Dr. Wallace's remarks as to the tooth-brush not being altogether an unmixed blessing, it is significant that the very next day after reading them there consulted me a man, aged 22 years, who had never in his life used a tooth-brush, and he had 32 sound teeth in his head.

I feel convinced that if Dr. Wallace's views are taken to heart by the medical profession we shall do much to diminish caries and other defects of the teeth. I, indeed, believe with him that we have it in our power to rear a race having teeth every bit as good as those of our primitive ancestors.

May I take this opportunity of saying that there is, in my opinion, a further indictment to be made against the use of soft food. I believe we have in the imperfect mastication which foods of this kind lead to a clue to the long sought-for pathology of adenoids—a subject with which I am dealing fully elsewhere.

I am, Sirs, yours faithfully,

Wimpole-street, W., July 9th, 1900. HARRY CAMPBELL.

To the Editors of THE LANCET.

SIRS,—The cause of caries of the teeth must be one of universal distribution and I have for years expressed my opinion that it is the universal consumption of bread made from flour deprived almost entirely of "earthy matter"; every particle of bran, which contains nearly all the above, being removed therefrom, the mother's blood therefore is deficient in the constituents necessary to properly build up and consolidate the bones and teeth of the fœtus. Every generation will, I fear, get worse and worse unless something can be done to improve the character of the bread consumed. Now I am writing may I be allowed to say that I have met with two cases in which mothers have vaccinated themselves accidentally from their babes; it is, therefore, I should think, not so very uncommon. I am, Sirs, yours faithfully,

Donington, Spalding, July 10th, 1900. E. W. JOLLYE.

"A PLEA FOR EARLY OPERATION IN CASES OF UNDOUBTED TUBERCLE OF THE LUNG."

To the Editors of THE LANCET.

SIRS,—The recent article in THE LANCET written by Mr. Foster Palmer on "A Plea for Early Operation in Cases of Undoubted Tubercle of the Lung" reminds me of a paper that I wrote some years ago but did not publish. By early operation I suppose the writer means such to attempt a radical cure, and not a palliative measure such as incision and drainage of advanced phthisis with pleural adhesions. None of the present procedures are well adapted for a radical excision, and such is rarely attempted, the fears of pneumothorax and hæmothorax deterring the surgeon from operating. But in the course of every lung case there must happen a time when, though the chance of medical cure is past, there still exists a time for radical excision before it advances too far. Let us take a case of a young person with phthisis in the apex of one lung which has gone on to cavity formation and in which there are as yet no pleural adhesions. If excision be desired how shall we proceed? In the article referred to the procedures are as follows. 1. To sew the pulmonary pleura to the costal pleura beyond the seat of the disease before operating. In such a case as the above this would be impossible. It would do in a case of large cavities with no pleural adhesions and some reasons against excision, such as the other lung affected, and then would only be as a preliminary to incising and draining. 2. To trust to previous existence of adhesions. This is not the case as above and if present would prevent a radical excision. 3. To excite artificial adhesions. This is dangerous, uncertain, and leaves a pathological lesion and a breeding-place for tubercle behind in a tuberculous subject. 4. Artificial inflation. This is unsatisfactory and the moving lung would hinder the operation. The method which I proposed was to collapse the lung artificially on the affected side by passing into the pleural cavity a suitable medium such as sterilised air, or preferably sterilised water or a weak antiseptic solution. This treatment is commenced some days before opening the chest and may be done by placing a small tube in one of the lower intercostal spaces and opening into the pleural cavity and fitted with tubing and stopcocks. The medium is passed in certain quantities daily and gradually, till the lung is sufficiently collapsed, and completed on the day of operation, the patient being thus slowly accustomed to using only one lung and being spared any sudden collapse. Now the pleural cavity can be opened as safely as a peritoneal cavity, due care being taken in the technique of the operation.

As regards the operation itself I suggest, first, a flap comprising all the tissues down to the costal surface of the costal pleura, and this being well demonstrated and all hæmorrhage

checked can be opened either by a small flap or by incision, semilunar or straight. The affected lung is now seized with forceps and drawn out and excised. The stitches necessary for this may be done as cobblers' double stitch. The pleura is now sewn up after the lung is replaced, the flap adjusted, and the operation completed; but before the costal pleura is sewn up the chest should be again filled with the medium.

If this medium is not absorbed and the lung repaired in due time aspiration might be performed. By this method even one whole lobe might be bodily removed after ligaturing its base and if the side was not subsequently filled with lung (other lobe or lobes and also by expansion of the lung of the other side), even after aspiration, thoracoplasty might be performed and the side of the chest adjusted to the size of the lung left.

By this method, not only the lungs, but also other thoracic viscera might be dealt with.

I am, Sirs, yours faithfully,

Newcastle-on-Tyne, July 6th. GEORGE LANE.

"LOSS OF MEMORY AND OF SENSE OF PERSONAL IDENTITY."

To the Editors of THE LANCET.

SIRS,—Your annotation on "Loss of Memory and of Sense of Personal Identity" in THE LANCET of June 9th, p. 1670, reminds me of a case which may be of interest in connexion with this subject.

Two or three seasons back, towards the end of cub-hunting and just before regular hunting commenced, a gentleman, a tall, strongly-built young fellow about 25 years of age, "trained on" with his horse from a station in the Midlands to another some 30 miles distant to meet the hounds. He made an early start—at that time of year hounds meet early—and possibly did not get much of a breakfast before starting. He rode through one run, not a particularly severe one. Then, as hounds were moving off to draw for another fox he found that he was lost. He had no recollection as to who he was, or where he had started from in the morning, of where he was, or of what hounds he was out with.

At a loss to know what to do, he rode up to another man out and asked him if he would tell him what pack they were out with. By one of those extraordinary coincidences which in a novel would be voted very far-fetched, the man he rode up to to inquire of was his own cousin. More remarkable was the fact that neither knew that the other was out; that they resided more than a hundred miles apart, and that while the patient had come by a train to the meet from some 30 miles west, his cousin had come the day before from a hundred miles east, and was out from the house of his host. The cousin, also, though recognising the patient at a glance, did not know where he was at the time staying. He, the cousin, in his turn, called to his aid his host and they put the patient in charge of a second horseman, directing him to ride close to the patient and not to leave him till he had deposited him at my house.

On my return from a journey I found the patient on a sofa in my consulting-room covered with blankets and my wife administering hot tea. He was very cold, his most prominent symptom being weak heart action—in fact, the usual symptoms of concussion and shock after a heavy fall. I had him put to bed and treated on general principles; and in the course of 24 hours his memory returned. Then I found that he had not long returned from Buluwayo and the Matabele rebellion, where he had been "just to see what was going on." He had suffered severely from malaria and it was pretty plain that the malaria was then by no means all out of his system. A couple of days before, riding a young horse, hunting, he had had one or two falls, but nothing to stop him. His heart action for the next 48 hours remained weak and unsatisfactory. I advised him that hunting was, for the present, absolutely out of the question for him. The chances of a recurrence of the symptoms, or of exhaustion from heart fatigue in a lonely place—where he might possibly lie in a state of exhaustion for hours before he was discovered—appeared to me to be altogether too great a risk to run. It was not a very pleasing opinion to him as he had just got a stud of horses together to begin the season with. However, he acted upon it and sent his horses up for sale. He made a complete recovery and has hunted regularly for the last two seasons and, so far as I know, has never had any return of the symptoms.

I am, Sirs, yours faithfully,

Stratford-on-Avon, June 14th, 1900. HARRY LUPTON.

"SIR W. FOSTER AND THE MEDICAL ARRANGEMENTS AT THE SEAT OF WAR."

To the Editors of THE LANCET.

SIRS,—In an annotation in your issue of July 7th you asked that I should furnish a reference to a statement by the late Professor De Chaumont which you have been unable to verify. If you will refer to the seventh edition of Parkes's Hygiene, edited by Professor De Chaumont, you will find on page 664 the following:—

"*Amount of hospital accommodation.*—This must not be less than 25 per cent. of the force with reserve tents in rear in case of need."

With reference to the mortality of 21 per cent. in the cases of typhoid fever in South Africa I said in the debate that if that represented the death-rate under the horrible conditions described by Mr. Burdett-Coutts, I believed that with proper care and nursing it might have been reduced to 12 per cent. I see no reason to alter that opinion. On the contrary, I am confirmed in it by the mortality of 7·38 per cent. recorded by Professor Victor C. Vaughan of the University of Michigan for the typhoid fever in camp in the United States army during the recent war and Brandt's mortality of 7·8 per cent. calculated on 19,017 cases.

I am, Sirs, yours faithfully,

House of Commons, July 11th, 1900. WALTER FOSTER.

*** We are obliged to Sir Walter Foster for so courteously giving the reference to Parke's Hygiene, 7th edition. To provide hospital accommodation in the proportion of 25 per cent. for an army such as ours in South Africa would mean at least 50,000 beds, a provision which it seems to us would seriously interfere with the mobility of the troops as a fighting force. Professor Victor C. Vaughan's figures are, we understand, those of cases treated in a stationary camp in their own country and not at the seat of war; while Brandt's figures refer, we believe, to cases which had not been exposed at all to the conditions of war. Will Sir W. Foster be good enough to compare the enteric fever statistics of the army in South Africa with those of the London Fever Hospital as given by Murchison, or with those of the Metropolitan Asylums Board for ages corresponding to those of soldiers, say from 20 to 30 years?—ED. L.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID COMMITTEE.

To the Editors of THE LANCET.

SIRS,—The outbreak of hostilities in China and on the West Coast of Africa must, it is feared, result in the early arrival of many naval, military, and other officers invalided home from the operations now being carried on in those quarters. Would you kindly allow me to make known through your columns that this Committee, originally formed to provide medical and surgical aid for those who have suffered in South Africa, will be equally prepared to render assistance to officers returning home from these other theatres of war. Applications should be addressed to the Hon. Arthur Brodrick, at Hampden House.

I am, Sirs, yours faithfully,

ABERCORN, President.

Hampden House, Green-street, W., July 11th, 1900.

CIVIL SURGEONS ON THE WEST COAST OF AFRICA.

To the Editors of THE LANCET.

SIRS,—In both THE LANCET and the *British Medical Journal* the Colonial Office is advertising for temporary civilian medical officers for an expedition—presumably military—to Coomassie. The emoluments offered for this service are £30 a month for a six months' engagement, free rations, a gratuity of ten days' pay for *every complete month served on the coast*—time occupied on the passage out and

home apparently not counting towards the gratuity—and a free passage out and home. When these terms are compared with the War Office remuneration to civilian surgeons in South Africa—viz., £1 a day, 3*s.* a day allowance, free rations, a horse and servant, two months' pay as a gratuity and a free passage out and home—and when one considers that the climate of this part of the West Coast is the most deadly along that most deadly littoral, while that of South Africa is, under ordinary conditions, perhaps the best in the world, the total inadequacy of the pay offered for the temporary but arduous and deadly work demanded is at once apparent. If there is any sliding scale of remuneration based on the risks involved and the nature of the work entailed, then the pay and allowances of these West Coast officers should be at least double those of their South African *confrères*. Men must be down on their luck indeed—professionally, socially, and financially—to accept this work at the rate offered, and I can hardly congratulate the Colonial Office on the type of medical man they are likely to obtain by their munificent offer.

I am, Sirs, yours faithfully,

July 10th, 1900. CANTAB.

"THE NATIONALISATION OF TRINITY COLLEGE, DUBLIN."

To the Editors of THE LANCET.

SIRS,—I do not think that a controversy can be profitably pursued on the lines of the letter of your correspondent "Irish Graduate." He asks me to say, "Is Trinity College to be the only place of collegiate education for young Irishmen?" To which I reply that I have not heard that anyone outside the walls of a lunatic asylum has suggested anything of the sort. My proposition is that the University of Dublin and its College should be absolutely free from even the suspicion of sectarian bias and should open their arms to alumni and intending graduates in arts coming from educational institutions of any religious type and that the education of those intending graduates should be left unrestrained to the respective institutions. Provision already exists, I believe, for the divinity education of these graduates in every religious community outside Trinity College, and I propose, simply, that that faculty shall share with others the position apart from Trinity which they occupy.

Your correspondent takes his stand upon the numerical predominance of Roman Catholics in Ireland, but I differ from him in the creed that university graduation or collegiate education should depend altogether on numerical preponderance. People who argue in this way must, to be consistent, object *in toto* to the education, on the lines of European civilisation, of any individual resident in an Eastern country like India, where the non-European community is enormously preponderant. Education ought to be cosmopolitan. I have already said that everyone knows that neither the Roman Catholic priesthood nor the authorities of Dublin University will permit desectarian education if they can help it. The whole question can, however, be settled by turning a deaf ear to the selfishly unreasonable demands of the priesthood and by peremptory desectarianism of Trinity College, and a Government endowed with a backbone could do it without trouble, but our present rulers are too busily employed in trying to catch the votes of the Nationalist party in anticipation of the general election to think much about Irish middle-class education.

I am, Sirs, yours faithfully,

A.M., M.D. DUB. UNIVERSITY.

ERRATUM.—In a letter headed "The Nationalisation of Trinity College, Dublin," which appeared in THE LANCET of July 7th, p. 50, the following correction should be made. Col. 2, par. 4, line 3: "A truly national university must be ....." should read, "A truly national university must *not* be ....."

LUNACY IN SOMERSET.—At a meeting of the Somerset County Council held on July 2nd it was reported that there were at Wells Asylum 339 male and 502 female inmates and at Cotford Asylum 195 male and 270 female inmates, making an aggregate total of 1306. For the corresponding quarter of 1899 there were 1284 patients, 532 males and 752 females.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending May 26th are as follows: remaining at the beginning of the week, 100; admitted, seven; discharged, 19; died, six; remaining at the end of the week, 82. The totals up to the end of the week are as follows: cases, 247; deaths, 89; discharged, 76; "contacts," 1407; "contacts" remaining, 115; cases among "contacts," seven.

The number of new cases during this week has been lower than in any week since that ending March 10th. The following table shows the weekly returns from the beginning:—

Week ending	Cases.	Week ending	Cases.
Jan. 27th	1	March 31st	23
Feb. 3rd	0	April 7th	29
,, 10th	0	,, 14th	29
,, 17th	0	,, 21st	16
,, 24th	2	,, 28th	27
March 3rd	2	May 5th	38
,, 10th	5	,, 12th	23
,, 17th	12	,, 19th	23
,, 24th	10	,, 26th	

This sudden and great reduction is not as easily accounted for as an equivalent rise would have been.

On May 1st, 2nd, 11th, 13th, and 21st cases of plague occurred at Manly. This town, which had remained uninfected, is situated at the northerly end of the fiord which forms the outer harbour and is about seven miles from Sydney. It can be reached by a journey of 13 miles by road which involves crossing water by two horse ferries; but communication is usually made by steamer. It is a favourite place of residence for people engaged during the day in Sydney and considerable numbers pass to and fro regularly; on Saturdays, Sundays, and other holidays many thousands of people resort there. The only feature which the four later cases had in common was their occupation at one of the wharves. The first patient was a shopkeeper in the town who had visited two warehouses in the neighbourhood of the infected wharves at Sydney three days before he fell ill; it was supposed at first, therefore, that he had been infected there, and it seems certain that his sole connexion with the Manly wharf consisted in his traversing it as a passenger. The ferry-boats carried rats and it was thought that some must have got ashore notwithstanding the precautions taken. Accordingly, as soon as the first case occurred steps were taken to trap and examine the rats on shore, and especially those about the wharf and the street nearest to it. Poison had long been laid for them. Many specimens, both alive and dead, were submitted and examined; nearly all had enlarged livers and spleens, but these signs could not be connected with plague after very careful examination, and were provisionally ascribed to phosphorous poisoning. The search was continued, it being assumed that where several cases of plague arise plague-rats must exist; and long after it began to seem likely it would prove interminable one putrid carcass was met with which afforded probable but inconclusive evidence of plague. Shortly afterwards a rat was sent in which furnished unmistakeable evidence of plague. Probably the trappers had worked too close to the wharf from which most of the rats had disappeared before they began their work.

May 28th.

The returns of plague in Sydney for the week ending June 2nd are as follows: remaining at the beginning of the week, 82; admitted, 17; discharged, eight; died, three; remaining at the end of the week, 88. The totals up to the end of the week are as follows: cases, 264; deaths, 92; discharges, 84; "contacts," 1502; "contacts" remaining, 122; cases among "contacts," seven. Since the Government offered a capitation fee for rats taken to appointed receivers nearly 25,000 have been paid for; the number for May was above 19,000. Most of them were taken in parts of the city and its neighbourhood which are known to carry infected rats, but a small proportion from more distant areas. To those who are aware of the multitudes in which rats swarm in and around Sydney these totals appear insignificant. However, it must not be forgotten that there was a time when the public had not been aroused to the necessity for killing rats

and that it continued long after the epidemic in man had become alarming.

A further supply of four litres of Yersin-Roux serum has arrived from Paris. At the hospital the opinion so far formed seems to be that very large quantities are necessary to produce decisive results; or, rather, that much larger quantities than have hitherto been used there are required. Still, the experience has been short, yet it is thought that intravenous injections do not produce a more striking effect than subcutaneous injections of twice the quantity—that is, of 40 c.c., reference being had merely to the immediate and not to the ultimate effect. Injection into the veins is made with a short needle; with a little practice this appears to be easy and the risk of penetrating both walls of the vein to be slight. At first the vein was dissected out; it is well that this tedious and rather delicate operation should be unnecessary.

June 5th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague.—More Patients for Paris.—The Water-supply of Bombay.

NOT since the epidemic broke out in 1896 has such a low death-rate from plague been recorded as for the past week. The mortality throughout India has declined to 319, as compared with 417 deaths for the week previous. Bombay city returns 97 deaths notwithstanding its rate of mortality is 67 per 1000 per annum—a total mortality of 1183 when it ought to be under 600. Calcutta returns 125 and these are almost entirely accounted for by the excess mortality. The figures for Calcutta prove for themselves that very few cases of plague occur in the city which do not get known to the authorities either before or after death. This accuracy in the returns is due to the system of inquiry and registration adopted. The deaths are carefully recorded every day at the burning ghats and burial-grounds. A list of deaths is made out and inquiry is made by medical officers into the circumstances of each death. If the clinical history obtained points to plague the death is returned accordingly. Constant inquiry and investigation in every part of the city bring to light a certain proportion—roughly, say, one-third—of living cases. Disinfection follows every doubtful death. This method has proved itself so accurate that taken over a long period the amount of plague recorded and the excess mortality balance each other. There has been no other epidemic disease to complicate the system and in view of the secrecy adopted by the natives it seems the only practicable method of procedure. Notwithstanding the satisfactory decline cases still continue to be returned from widely scattered districts. Bengal gives 37, the Bombay Presidency 32, Karachi 12, and Aden five.

I regret to hear that no less than ten privates of the 1st Royal Scots Fusiliers and three drivers and gunners of the 24th and 52nd Field Batteries have sailed for treatment at the Pasteur Institute at Paris on account of bites from animals suspected to be suffering from rabies.

After a heavy fall of rain with storms in various places the weather throughout India has again been unpropitious and the real monsoon can hardly be said to have arrived. The south-west current is reported to be weak and unsteady and the welcome rainfall on the west coast of the peninsula is declining.

I have from time to time had occasion to report upon the water-supply of Bombay. Generally of abundance, the quantity has been seriously affected by last year's drought, and while hitherto considered unquestionable in quality it is now found to require filtration. The plan recommended is to construct covered filters outside the reservoirs. Though this will prove more costly than placing them inside the distributing basins there would be greater facility in looking after and maintaining the filters as the catchment basins are some distance from the city. The municipal authorities are justly proud of the water-supply and there is little doubt that with the precaution of properly constructed and well-maintained filters Bombay will be supplied with water second to none in the dependency. As I pointed out in a previous letter, there is some evidence that the amount of enlarged spleens (as representing the malarial condition of a place) is influenced considerably for the better by filtration of the water-supply. An explanation of this is still wanting.

June 24th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Housing Problem.

MANCHESTER and Salford are each confronted with the perplexing and, so far as can be seen at present, almost insoluble problem of how to provide decent and healthy house accommodation for those who can only afford to pay 4*s.* or perhaps 5*s.* a week rental. It is forced on them by the necessity there is for clearing away insanitary dwellings—which unhappily are just those most apt to be overcrowded—if the public health is to be maintained or improved. For the last 15 years the corporation of Manchester have been gradually doing away with back-to-back houses. They are ill-ventilated, and the closets are oftener bad than not, sometimes opening on to the street, sometimes being built into the side of the house, with perhaps walls soaked and leaking into a living room and with a bedroom over. To live healthily under conditions even somewhat better than these would be difficult for the most cleanly, but, as a rule, such dwellings are occupied by the lowest of the people who by their own careless and filthy habits go far towards securing a heavy death-rate. The Sanitary Committee have during the last 15 years closed 3522 insanitary houses, but the occupants have been re-housed by the corporation, generally, however, having had to pay a higher rent. In many cases, no doubt, the original tenants have gone elsewhere or crowded into houses already tenanted, and their places have been filled by a somewhat higher class of working people. This question was discussed at the last meeting of the City Council, and the proposed closing of certain houses in Hulme by the Sanitary Committee was referred back. The mover of the amendment said that the work of demolition proceeded more rapidly than the provision of new dwellings and hence overcrowding prevailed. Within a recent period he stated that out of 583 houses closed in Hulme 389 had been demolished and over 1500 people had had to go into houses where families were already in occupation, and that of the 13,000 houses built in Manchester during the past 10 years none were to be let at 4*s.* a week, which was the highest rent the people he referred to could pay, though they were for the most part honest members of the labouring classes. With the increasing value of town sites it seems that four-roomed cottages cannot be built to let at 4*s.* a week without loss. The speaker advocated the provision of what are called "barrack dwellings." Those that have been built in Manchester are tenanted, but it is a complaint that the rooms are too small, which might be avoided in the future. One of the objections to these buildings of many storeys is, not that the parents have to go up and down so many steps, but that it increases the difficulty of the children getting proper air and exercise. The same problem troubles our neighbours of Salford. In course of time some hundreds of dwellings have been demolished, and builders are now beginning to use up the old bricks to provide those displaced with new houses. But the old rent for the four-roomed houses was 3*s.* 6*d.*, while that for their less roomy and less commodious successors will be 6*s.* 6*d.* The addition of 2*s.* or 3*s.* a week to the rent is a serious matter to a woman, say, who only has 12*s.* or 14*s.* a week for household expenses. There is no great wonder that our town-bred population grows up weakly and stunted and that the "corner boys" and "hooligans" of our streets excite pity as specimens of a decaying race and disgust as an illustration of the results of our methods of bringing up our boys. It is not surprising that scarcely one-half of our town-bred young men come up to the low standard of physique required in our recruits. Nor is it likely to alter for the better while life in the slums is what it is and while life in the barrack flats must be too confined for the healthy growth and development of the coming race. Easy and cheap transport to the outskirts of our towns would do away to a great extent with the need for the working classes to live close to their work. Houses would be cheaper than in town and the children would grow up under more natural and healthy conditions than at present, much to their advantage in mind and body. In these days, when peace and goodwill among the nations seem farther away than ever, one cannot but view with concern the rapid physical, and, one fears, moral degeneracy of our town population.

The late Dr. D. J. Leech.

Manchester has suffered stroke upon stroke of late from the hand of death, and the medical profession is left much the poorer by the loss of a physician so able, so conscientious, and so universally respected as Dr. Leech. His painful illness was borne with fortitude and resignation touching to witness in one whom we had known for years as an almost perfect illustration of strength and energy, of the sound mind in a sound body. It is remarkable that three, if not four, members of the infirmary staff should have fallen victims one after the other to some form of the same disease.

July 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Public Health Congress, Aberdeen.

THE official programme now issued shows that the proceedings of the Congress of Public Health to be held at Aberdeen will last from August 2nd to 7th inclusive. The patron of the Institute (the Royal Institute of Public Health) is Her Majesty the Queen. Lord Balfour of Burleigh, Secretary for Scotland, is patron of the Congress and Lord Aberdeen is the president, while Lord Provost Fleming (Aberdeen) is the honorary president. Professor W. R. Smith, M.D. Aberd., D.Sc., F.R.S. Edin. (London), is the president of the Institute and Mr. Henry C. Jones (197, High Holborn, London, W.C.), is the honorary secretary; Professor Matthew Hay, M.D. (Aberdeen), and Mr. Kenneth Cameron (chief sanitary inspector, Aberdeen), are the honorary secretaries of the Congress. The various sectional presidents are as follows:—Preventive Medicine and Vital Statistics section: Dr. W. J. Simpson, Professor of Hygiene, King's College, London. Bacteriology and Comparative Pathology section: Dr. D. J. Hamilton, Professor of Pathology, University of Aberdeen. Chemistry and Meteorology section: Dr. C. Hunter Stewart, Professor of Public Health, University of Edinburgh. Architecture and Engineering section: Mr. John Honeyman, R.S.A., F.R.I.B.A., architect, Glasgow. Municipal and Parliamentary Hygiene section: Dr. Robert Farquharson, M.P. The various conferences will meet in Marischal College, commencing on Monday, August 6th, at 11 A.M. The president of the Medical Officers of Health Conference will be Dr. John C. McVail, medical officer of the counties of Stirling and Dumbarton; of the Sanitary Inspectors' Conference, Mr. Peter Fyfe, F.R.S. Edin., chief sanitary inspector of Glasgow; of the Veterinary Surgeons' Conference, Mr. W. Williams, F.R.C.V.S., principal of the New Veterinary College, Edinburgh.

The Illness of Professor Ogston of Aberdeen University.

A telegram from South Africa recently received in Aberdeen stated that Professor Ogston's illness was enteric fever, that he was still a patient in hospital at Bloemfontein, but was progressing favourably.

July 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Principal Medical Officer in Ireland.

DURING the absence on leave extending to August 4th of the Principal Medical Officer in Ireland his duties will be performed by Lieutenant-Colonel F. G. Adye-Curran, Royal Army Medical Corps.

The Hospital at Bloemfontein.

In connexion with the treatment of the sick and wounded at Bloemfontein it is interesting to note that the Raadzaal (Parliament House) there has been converted into a hospital and is under the charge of Colonel W. W. Kenny, R.A.M.C., well known in Dublin. Under him are Surgeon Henry Moore of the City of Dublin Hospital (a volunteer), Lieutenant Archer, R.A.M.C. (also from Ireland), with Surgeon Williams of London. Eight nursing sisters are attached to the hospital in addition to the usual staff of orderlies.

Military Manœuvres and the Belfast Water-supply.

At a meeting of the Belfast Water Commissioners on July 5th attention was publicly called by one of the members to the statement that part of the Mourne range of mountains had been scheduled as a portion of the area over which the summer military manœuvres are to be conducted, and that this part so specified actually included the catchment area purchased by the Belfast Water Commissioners. The Water Commissioners have (or will shortly have) paid a million of money in connexion with this scheme, and in order to ensure the purity of their catchment area they had bought it up, minerals and all. Very naturally the Water Commissioners, seeing what has taken place recently in Africa, protest very strongly against any risk of their catchment area being in any way interfered with owing to the great risk of the sanitary conditions accompanying an army in the field, and they call upon the Belfast Members of Parliament and the city corporation to use their influence to prevent such an occurrence taking place as their catchment area being made a camping ground for military manœuvres. Some years ago, the Commissioners having restrained the colonel of a regiment stationed in Belfast from washing his dogs in one of their reservoirs, that military authority in martial dudgeon refused to allow the regimental band to play any more in the pleasure grounds of the waterworks, whereupon the Commissioners were much blamed by the Press for needlessly interfering with the recreations of the people. The Press, however, it is hoped now will uphold the Commissioners in their rightful efforts to prevent defilement of their catchment area at the Mourne Mountains.

North of Ireland Branch of the British Medical Association.

The twenty-second annual meeting of the North of Ireland Branch of the British Medical Association was held in the town-hall, Portrush, on July 5th. From the annual reports it appears that the society is in a most flourishing condition, there being 271 members, of whom 153 are country and 118 from Belfast. Financially there is a balance in the treasurer's hands of £13 18*s.* 9½*d.* The following office-bearers for 1900–1901 were then elected:—President: Professor Byers. Vice-Presidents: Dr. J. S. Darling (Lurgan) and Professor Lindsay. Secretary: Dr. W. Calwell. Treasurer: Dr. George Gray (Newcastle). Members of Council—Country: Dr. E. C. Thompson (Omagh), Dr. J. Stuart (Ballymena), Dr. J. C. Martin (Portrush), Dr. J. C. Hall (Monaghan), Mr. St. George (Fishburn), Dr. Agnew (Lurgan), Mr. R. Gray (Armagh), and Dr. D. Gaussen (Dunmurry). Belfast members: Dr. John Campbell, Dr. A. Dempsey, Professor Sinclair, Dr. M'Kisack, Professor Whitla, Dr. McCaw, Dr. E. C. Bigger, and Dr. A. B. Mitchell. The President (Dr. J. C. Martin) read an interesting paper on Portrush from a Medical Point of View.

The Samaritan Hospital, Belfast.

A summer fête and fancy fair was held at Norwood Tower, Belfast (kindly lent by the ladies and gentlemen of the Henderson family who placed their beautiful grounds at the disposal of the promoters of the undertaking), on July 6th and 7th. The object was to clear off a debt from the Samaritan Hospital. Dr. St. Clair Boyd, one of the surgeons to the hospital, has offered in the most generous manner to be responsible for any deficiency in case the debt is not cleared off. A sum of about £300 has been raised.

July 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Last Lecture of Professor Potain.

ON Tuesday, July 3rd, at 10 A.M., Professor Potain in the theatre of the Charity Hospital gave his last lecture upon Clinical Medicine. The rules as to age limit are inflexible. Hospital physicians must retire at the age of 65 years and hospital surgeons at 62. If, however, the physician is also professor in a clinic he may hold his appointment up to the age of 70 years, and if he is a member of the institute he may continue until he reaches the age of 75 years. Professor Potain, who is 75 years of age, has thus gone to the extreme limit which his accumulated offices allow, and he resigns his chair while still in full possession of his faculties and enriched by his long experience. Few medical careers have been so worthy as that of the venerable professor. A consummate clinician whose labours on diseases of the heart and lungs have gained him a world-wide reputation; an exemplary professor who for 30 years without a break took up his parable before an audience composed of listeners of every

nationality very many of whom were past masters in their art; a physician who for 40 years arrived at 8 A.M. to the minute in his wards when he saw all his poor patients whose claims were never neglected for those of the rich and mighty; a public man whose retirement meets with universal regret and who is everywhere respected; in addition to all this he is absolutely upright and kind-hearted to a degree which no one who knows him can forget. Overwhelmed as he was by requests for a consultation he never would raise his fees—a fact with which his younger colleagues would sometimes reproach him—but whoever asked for his opinion, even among the humblest, was sure of getting it, and that, too, very often without any fee. These, then, are the reasons why throughout France no physician is regarded with such practically filial respect as "Father Potain," to give him the name by which he is generally known. When, therefore, the day dawned upon which one so loved had to resign his chair and his hospital work it is easy to conceive the cruel wrench which the parting would give him. Such a feeling was widespread, and by no concerted action but on their own initiative all his pupils and many of his friends attended his last lecture. There in that throng, so evidently permeated by an emotion no less marked because restrained, were Professor Bouchard, Professor Dieulafoy, Professor Guyon, Professor Brissaud, Déjerine, Gaucher, Oulmont, Gourand, Moutard-Martin, Duflocq, Vaquez, Marey, Teissier, and many more old pupils who have now become teachers. Professor Potain began his lecture just in his usual calm way and pointed out the remarkable harmony which existed between the results of a radiographic examination of the heart and the results obtained by stethoscopy—it seemed as if he wished his last words as professor to be concerned with his favourite study of the heart, by doing homage to the modern discovery, owing to which that study had entered on a new road. Eleven o'clock struck, the master stopped, and in the midst of a dead silence announced that he had given his last lecture. "I wish," he continued, "to say a word or two in memory of Corvisart who, 100 years ago in this very theatre, created the first course of clinical medicine in France. I wish to thank my colleagues, my pupils, my friends, whom——" His voice failed and he stopped with his eyes full of tears. Thunders of applause burst through the theatre, during which his pupils rushed towards him and escorted him to the door. There the Professor fell into the arms of his old pupil Dieulafoy, who warmly embraced him. He then went up the staircase, which was lined with old pupils and friends, whom he saluted and all of whom were visibly moved. Then slowly and sadly crossing the quadrangle, he left the hospital for the last time.

Definite Lesions in Prehistoric Bones.

M. Zambaco of Constantinople recently showed before the Academy of Medicine a series of photographs of human bones collected in Upper Egypt and dating back some 8000 years. Alterations of a destructive or hypertrophic nature, such as suppurative osteitis, exostoses, eburnated surfaces, and the like were evident upon the bones of the skull, the limbs, and the vertebral column. Some of these M. Zambaco considered were due to syphilis and others to tuberculosis. M. Fournier said that he did not consider that the lesions of which M. Zambaco had shown photographs gave any definite evidence of having been caused by syphilis. It is next door to impossible to affirm the existence of syphilis simply from the alterations exhibited by the bones, for a variety of diseases give rise to alterations in the bones exactly similar to those produced by syphilis. Not only do ordinary injuries give rise to exostoses exactly comparable to those produced by syphilis, but varicose ulcers give rise to hyperostosis of the tibia at the border of the ulcer which differs in no way from syphilitic periostitis. M. Fournier, therefore, was of opinion that a simple inspection of a bony lesion was not enough to enable the observer to determine its origin.

July 10th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in Rome.

AT a recent meeting of the Società Lancisiana di Roma Professor T. Gualdi, chief medical officer of the Bureau of Hygiene, gave some interesting particulars regarding tuberculosis in Rome. While, he said, the population of the city had increased from 350,000 in 1885 to over 508,000 in 1899 the number of cases of tuberculosis had remained about the same, and it might therefore be inferred that there had occurred a relative diminution in the prevalence of the disease. But even if the proportion had remained the same there would still have been cause for satisfaction, because as the population increased so did the sources of contagion. Pulmonary tuberculosis, which on account of the greater ease of diagnosis afforded a better guide than other forms, accounted for over 900 deaths out of a total for all forms of 1500. A diminution had taken place in the number of abdominal, meningeal, glandular, and miliary cases, which (except the last) were the usual index of infection by the digestive tract. In regard to the morbidity there was little to guide one since the hospitals reported only the gravest cases. The number of cases of pulmonary tuberculosis might, however, be put down as being at least three times as great as the number of deaths—in other words, it might be said that every year there were 3000 phthisical subjects in Rome. A good deal had been done in the direction of prophylaxis, but much remained to be done. Tuberculosis of animal origin had been reduced to a minimum. No tuberculous meat was eaten and milk no longer presented serious dangers. Santori had found bacilli constantly present in the sediment of the milk supplied in Rome which resisted acids after staining with Ziehl's solution and yet were not tubercle bacilli. These were constantly present in the normal fæces of the cows. But no bacilli capable of causing infection were found. The hygienic condition of the dairies had improved immensely. The use of tuberculin had become general and gave splendid results. On notice being given by the authorities of the slaughterhouse of any cow with tubercle the cows of the dairy from which the animal came were at once tuberculinised. All cows were now so examined once a year. At first there was a great difference between the number of cases in oxen and the number in cows, but now there was the same proportion in both—viz., 6 per cent.—of those slaughtered, and in the greater number the tuberculosis was circumscribed. Since cattle caught the infection from man it was well to keep them out of the city, although this rendered supervision more difficult. In regard to disinfection this had been carried out during the last five years in all houses where death from phthisis had occurred and in the houses of all phthisical patients sent to hospital. Excellent results had been obtained by washing the floors with boiling caustic soda and whitewashing the rooms with lime. All second-hand furniture and carpets sold ought to be disinfected and eventually this would be done. The isolation of patients, Professor Gualdi thought, would not be secured without a vigorous propagation of the doctrine of infection. In the hospitals it was already well carried out and even in tenement houses it began to be practised as its necessity became better understood. In this connexion he dwelt on the importance of early diagnosis. In all public places in Rome placards forbidding spitting on the floors had been put up and spittoons supplied, and the same had been done in the houses of the working-classes. Instructions in the various hygienic measures for preventing the spread of the disease had been issued to the public. Professor Gualdi added that he believed the low relative proportion of cases of tuberculosis in Rome to be due to the backward state of industries, with the developmeet of which an increase in the number of such cases might be expected. In the discussion which followed the reading of Professor Gualdi's paper several speakers, while praising the work already done by the Municipal Bureau of Hygiene, commented on the absence of precautions against infection in the schools, and some advocated a system of medical inspection of the school children for the purpose of eliminating all tuberculous subjects, for whom special permanent schools—sanatorium schools, as suggested by Baginsky at the Congress of Naples—should be established. It was even urged that the Bureau of Hygiene should take up the question of the gratuitous feeding of school children by the Government. One speaker deplored the insanitary condition of the public offices, courts of justice, post offices, &c., and was not surprised that until the authorities provided more efficaciously for the cleanliness of the places immediately under their care there should be a disposition on the part of the public to ridicule the prohibition against spitting. In the course of his reply to these criticisms Professor Gualdi remarked that a great practical difficulty in the way of securing obedience to the injunction against spitting was the

want of a good portable pocket spittoon. The responsibility for the hygiene of public offices lay, he said, not with the municipality, but with the Government. He entered heartily into the scheme of school canteens which had been established in Belgium at trifling cost. He admitted the deficiency of hygienic supervision of the schools, the need of special schools, of sanatorium schools, &c., but the resources of a Municipal Bureau of Hygiene were unequal to the task of carrying out such a vast programme.

The Anti-malarial Campaign.

The anti-malarial campaign in the Agro Romano has now fairly begun, the eight ambulances organised for it by the Red Cross Society having left Rome for their various stations at the end of June. A day or two previously they had been inspected by the President-General of the Society, Conte Taverna, who was accompanied by Conte Della Somaglia, President of the Roman Committee, and by the medical inspector, Professor Postempski. The wagons were constructed at the arsenal of Turin expressly for this service and are made in such a way as to be convertible in time of war into transports for the wounded. Every wagon, in addition to the ambulance stretchers, carries three cases containing surgical instruments, medical appliances, and medicines (compressed and liquid), and a fourth case with miscellaneous stores and a saddle for the use of the medical officer in the event of his services being required at places not accessible by carriage. The *personnel* wear the uniform adopted by the Red Cross Society for Africa—flannel tunic and trousers with helmet and alpine boots for the officers, and linen coat and trousers with helmet for the nursing attendants. The medical officers, of whom there are eight, are armed with revolvers. On July 1st, at daybreak, the ambulances started on their various rounds, and already the first reports of the work done begin to reach the Bureau of Hygiene. For the present, and until the malarial season commences in earnest, this work will be chiefly in the nature of practice, to familiarise the medical officers with each locality and the best way of dealing with its particular needs. Nevertheless, on this the first day of the campaign a large quantity of preventive remedies were distributed and a couple of bad cases of malaria were admitted into the Hospital of Santo Spirito. Even the small experience already gained shows that this crusade against the deadly foe which yearly exacts so heavy a tribute from the fever-stricken peasantry of the Roman Campagna will be the means of relieving much suffering and of saving many lives. To the same humane object the series of experiments which the Society for the Study of Malaria are again inaugurating in Latium for the malarial season now commencing will no doubt likewise contribute. These experiments will be of a similar kind to those carried out last summer along the Mediterranean and Adriatic railways with such encouraging results. Some 26 of the houses of the employés along the same lines of railway, all in localities known to be highly malarious, will be selected, and the doors and windows will be closed with wire gauze to prevent the entrance of anopheles. The men on night duty will wear special coverings for the head and hands to protect them from the bites of mosquitoes, and will have preventive medicines administered to them. Similar measures will be adopted by the Acqua Marcia and the Rome-Tivoli Electric Traction Companies for their stations and workpeople, and an attempt will be made to induce the peasantry in the most malarial zones, such as Cervelletta, Castella di Velletri, the Pontine Marshes, &c., to adopt like precautions, wire gauze for the windows of their houses and huts being supplied to them. The Caetani family have had a moveable shelter constructed furnished with mosquito nets and all the necessary protective paraphernalia, which will be sent with the workpeople to the various places where the mowing, ploughing, and reaping are successively carried on thus to afford them a safe sleeping-place during the night-time. While these experiments are going on in the Agro Romano other series of a similar nature will be prosecuted in the Tuscan Maremma and in the provinces of Salerno and Bari. All the results will be collected and compared in the hope of gaining information and devising practical measures which may prove helpful in protecting the labouring classes against the ravages of malaria.

Small-pox in Piedmont.

There appears to have been no recrudescence of the outbreak of small-pox with which Italy was threatened last April through the landing at Naples of a number of infected persons belonging to a large party of American tourists, but two cases of hæmorrhagic small-pox imported from Toulon and Marseilles are reported at Cuneo in Piedmont. One case has proved fatal and in the other the patient is not expected to recover. Prompt measures were taken to prevent any spread of the infection.

July 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Ice Trust in New York.

MUCH indignation has been aroused among the inhabitants of New York by the action of the trust which controls the sale of ice in the city in raising the price of that indispensable commodity during hot weather to a figure almost prohibitive to the poor. Owing, however, to the stand taken by some of the New York daily journals, notably by the *New York Journal* and by the *World*, the prosecution of this obnoxious scheme has been frustrated, and, furthermore, its promoters and the more influential of the shareholders in the company, among whom were the Mayor of New York and other city officials, have been publicly pilloried and sharply brought to book. If the project had been carried out much suffering would have been entailed on the residents of the poorer districts of New York, where in the summer the heat is often oppressive to a degree and where ice is a necessity for the preservation of food. Dr. Dwight Chapin, writing on the matter in the *New York Medical Record* of June 9th, says:—"It is estimated that there are 146,600 children under the age of three years in the boroughs of Manhattan and Broux, or 6·72 per cent. of the whole population. This immense number subsists principally upon milk. Recent studies show that if cow's milk can be properly cooled it will keep a considerable time and is much better than relying too largely upon superheating. Here is where the subject of ice comes properly under the physician's notice. Any difficulty in the free procuring of ice during the heated months, whether from a natural scarcity of this article or from a cornering of this staple by commercial greed, is a public calamity."

Plague in San Francisco.

The plague in San Francisco, owing doubtless to the vigorous measures taken for its suppression by the United States Marine Hospital Service and by the San Francisco Board of Health, has apparently been, if not completely eradicated, at least kept well under control. Dr. Kinyoun, of the Marine Hospital Service, San Francisco, states that from March 7th to June 2nd there have occurred 11 deaths from plague in San Francisco. In 10 of these the diagnosis has been confirmed by bacteriological examination. There were at the time of the despatch of the report three suspected cases under investigation. In order to prevent dissemination of the disease strict measures of inter-State inspection are in vogue. The Chinese and Japanese object very strongly to the cordon placed around their quarters as well as to the inoculation with Haffkine's serum, to which they are compelled to submit, arguing that they are being subjected to an unfair discrimination. So strong is this feeling among the members of the yellow race in San Francisco that a suit has been brought by them to test the validity of the existing law and to procure an injunction against the local authorities to cause the abandonment of the cordon around the Chinese quarter. Dr. Kinyoun, in his report to Surgeon-General Wyman, says that the local press is still attacking the Board of Health in every way it can, and is fully and cordially supported by one of the mercantile associations of the city. They have issued a circular which is now being scattered broadcast over the city and, I presume, over parts of the United States in which it is stated that the Federal authorities joined with the State and local authorities have stated that no plague exists in San Francisco. Dr. Kinyoun has contradicted this assertion and declared that plague infection does exist in the Chinese quarter and will exist until a strong, determined, and concerted effort is made to eradicate it.

Death of Dr. Paul Gibier.

Dr. Paul Gibier, the head of the Pasteur Institute in the United States, died from injuries received in a runaway accident at Suppern, New York, on June 9th. He was born in France in 1851 and after graduating at the medical side

of the University of Paris, became assistant professor of comparative medicine. In 1885 the French Government sent him to Spain to study the outbreak of cholera there, and in the following year he was sent to the South of France to study the same disease. In 1888 the same Government sent him to Havana to study yellow fever. On his way home he stopped in New York. He returned the next year, 1890, and started the Pasteur Institute in this country, a specialty of which was originally the preventive treatment of hydrophobia.

June 29th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

THE epidemic of bubonic plague would appear to be slowly subsiding in Australia. In New South Wales 248 cases have occurred to date of which 83 proved fatal. In Sydney the disease shows a tendency now to locate itself in the Chinese quarter, in which eight of the more recent cases occurred with seven deaths. Vigorous measures have been taken to improve the sanitary conditions. The Government has taken over the infected wharves and they are in course of demolition, the timber being burned and the accumulated filth under the wharves being removed in punts. Inspection and cleansing of the city and also destruction of rats are still going on. In Melbourne the municipal authorities are being galvanised into activity in the same way. Additional inspectors are being appointed and the scavenging operations are more efficiently conducted. No cases of plague have occurred in Victoria for a period of 11 days and of the nine cases that have occurred (four being in one family) only one (at Geelong) proved fatal and, indeed, was only diagnosed post mortem. As usual doubt has been cast on the diagnosis in all the cases, but its correctness seems to be unquestionable. Several cases have occurred in Brisbane and at Rockhampton in Queensland. Western Australia is declared to be free from cases. Two cases are reported from Adelaide. In many instances it has been impossible to trace the method of contagion, but the observations of the health authorities, so far as they go, support the views of Simond as to the part played by fleas.

Metropolitan Hospitals and their Needs, &c.

Recently a deputation waited on the Colonial Secretary of New South Wales with reference to extending the Prince Alfred Hospital, Sydney. It was stated that for several years the demands for accommodation had increased to such an extent that more beds were urgently required. The hospital had the ground and the plans ready for the erection of two new pavilions providing 120 beds. The administrative arrangements were such as to suffice for working the increased number of beds and the ratio of cost would thus be materially lessened. If the request were not granted patients must be turned away. The institution had been originally built with a view to its enlargement as the population of the city increased, and the time for its enlargement had now arrived. In reply the Minister said that he fully recognised the increasing need for more hospital accommodation. Not only had the population increased but the hospitals were more popular. He fully appreciated the good work which the hospital did and he would seriously consider the matter and bring it before the Cabinet, and probably they would place a sum on the estimates to enable the work to be carried out. The deputation also asked for a further sum of about £5000 to carry out improvements in the existing buildings and to clear off a deficit on the nurses' home. The Minister promised a favourable consideration of this request also. In Melbourne the finances of the leading hospital are in a bad way, chiefly owing to the action of the Government some years ago in reducing its annual grant to the hospital by £2000. The annual expenditure has exceeded the revenue by about that amount ever since, until now the debt of the Melbourne Hospital is £18,000, and the committee has decided that if the income is not increased some of the wards must be closed. An effort has been made to clear off the debt by public subscription, &c. A large bazaar was held which realised £8000, and Mr. G. Iliffe subscribed £1000 on condition that £20,000 were raised by subscriptions of £1000 and £500. Towards this amount £7700 have been given, and it is hoped that the balance will soon be raised. The question of admitting paying patients into public hospitals has also been much discussed of late, both in Sydney and Melbourne. Mr. E. T. Thring of Sydney in his address as retiring President of the New South Wales Branch of the British Medical Association, condemned the practice, asserting that such hospitals entered into unfair competition with strictly private hospitals, and further charged the members of the staff of such institutions with acting unfairly to the general body of practitioners. The *Australasian Medical Gazette* took up the matter and severely denounced the practice, and appealed to the members of the staffs of the hospitals in question to remedy the abuse. In Melbourne the *Argus* newspaper made much the same statement, giving a full account of the methods adopted at all the different hospitals. The authorities at St. Vincent's Hospital in Melbourne made a reply to the effect that as they receive no aid from the Government they are compelled to add to the income received from public subscriptions by taking a limited number of private patients into wards set apart for the purpose, and that the nursing and administrative work being all done gratuitously by the Sisters of Charity they make a considerable profit on the private patients and prevent imposition on both the charity and the profession in many cases.

The Lunatic Asylums in Victoria.

The Melbourne press have been attacking the administration of the Lunacy Department in Victoria, both the *Age* and the *Herald* having published articles on the subject. The main points brought out are—that in proportion to the population there are more lunatics in Victoria than in any other English-speaking country; that there has been a steady decline in the percentage of recoveries among the patients admitted to the asylums—in the early part of the last decade more than half were cured, now less than one-third recover; and that there is no receiving-house where doubtful cases can be kept under observation, and no proper provision for paying patients, private asylums having been abolished by Act of Parliament. The administration defects are all ascribed to the false economy practised by successive Governments. It is also alleged that the medical officers are for the most part incompetent, the inadequate pay and civil service conditions of promotion by seniority failing to attract good men. As usual in newspaper articles of the kind there is a good deal of truth mixed up with a good deal of exaggeration and misstatement in these charges. When the financial depression came on the colony the Lunacy Department, like every other State department, was retrenched and economy was carried to an extent that was unfair to the medical staff and to the patients; and the inadequate pay and difficulties of successful administration do unquestionably prevent the best men in the profession from entering the service. Still there are some very capable and skilled men on the staffs who take the keenest interest in their work and in teaching the students of the medical schools who attend at the metropolitan hospitals for the insane. The report of the Inspector-General for last year will also show a great increase in the proportion of recoveries.

The Victorian Branch of the British Medical Association.

At a meeting of the Goulburn Valley Sub-branch of the Victorian Branch of the British Medical Association, held on May 7th, the following resolution was carried unanimously:—

> Having heard read the evidence in the O'Hara case, we, the members of the Goulburn Valley Sub-branch in regularly notified meeting assembled, unanimously resign from the Victorian Branch (but not from the British Medical Association), as we entirely concur in the action of the late Council.

The Ballarat Sub-branch also passed a resolution approving of the action of the late Council. The South Australian Branch, at a well-attended meeting held on May 31st, unanimously passed the following resolution:—

> The South Australian Branch of the British Medical Associatio sympathise with the late Council of the Victorian Branch of the British Medical Association in their endeavour to uphold the dignity of the profession in the matter of the "Silenette" investigation; and are of the opinion that they could not have acted otherwise than they did in resigning their positions after the insufficient vote of the 21st March, 1900. That our Representative on the General Council, British Medical Association, be requested to bring the decision of this Branch before the said Council.

Carrasquilla's Serum Treatment of Leprosy.

In the *Intercolonial Medical Journal of Australasia* for May is an account of a very exhaustive investigation by

Dr. F. Tidswell of the value of the serum treatment of leprosy devised by Carrasquilla of South America. The mode of preparing the serum is described as are the results of the treatment, which did not accord with the results stated by Carrasquilla. During the treatment tubercles and maculæ remained and increased, anæsthesia and nerve thickening persisted, and alopecia and defects of sight, &c., were not improved. The disease, far from being cured, did not appear to be even ameliorated, and after nine months' persistent trial the patients declined further treatment.

June 1st.

Obituary.

DANIEL JOHN LEECH, M.D., F.R.C.P. LOND, D.SC. VICT.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE OWENS COLLEGE, MANCHESTER; CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; AND REPRESENTATIVE OF VICTORIA UNIVERSITY UPON THE GENERAL MEDICAL COUNCIL.

THE death of Dr. Daniel John Leech, the well-known Professor of Materia Medica in Owens College, Manchester, following close upon the death of Professor Thomas Jones, inflicts a double shock upon medical circles in Manchester. Like that of his colleague Dr. Leech's death was premature, but his friends had known for three months that the end was only a matter of time, as he was suffering from malignant disease of the stomach.

Dr. Leech was born 60 years ago at Urmston, being the second son of the late Mr. Thomas Leech, a medical practitioner in that city, and the younger brother of Sir Bosdin Leech, the ex-Lord Mayor of Manchester. It is interesting to note that Dr. Leech's original family name was Bosdin, for he belonged to a branch of the old Cheshire family of that name which adopted the name of Leech—at least, so it is said—because of the persistence with which its members distinguished themselves in medicine. The late Dr. Leech has added lustre to his medical name. He entered the recently founded Owens College, Manchester, at the early age of 14 years, and six years later, in 1860, he matriculated in the first division at London University. He was already an advanced medical student, wanting only the final examination to qualify him, his medical studies having been pursued in the Manchester School of Medicine and also, as was the habit in those days, as the assistant of a general practitioner in the city. His career as a student was a successful one and was frequently rewarded with prizes. In 1861 he qualified as M.R.C.S.Eng. and L.S.A. In the following year, after a short sojourn in Paris, the anatomical schools of which city were famous in the "sixties" for the excellence of their teaching and the facilities afforded to the students for practical work, he became demonstrator of anatomy in the Manchester Medical School. This post he held for two years, and in 1864 came up to London where he entered his name for classes at St. Mary's Hospital, upon the honorary staff of which were to be found at that time the names of Dr. James Alderson, F.R.S., Dr. Tyler Smith, and Mr. J. Lane, all of whom had a wide reputation. Returning to Manchester he was taken into partnership by the medical practitioner whose assistant he had previously been, and in 1868 he graduated in London University as Bachelor of Medicine, obtaining first-class honours in gynæcology. In 1870 he was appointed physician to the Hulme Dispensary, and three years later he became assistant physician to the Manchester Royal Infirmary, with which institution his name from that day forward was honourably associated. His excellent work both as teacher and clinician met with ready recognition; his grasp of clinical medicine was firm and his power of imparting instruction great, and in particular he interested himself in the study of materia medica and therapeutics, a branch of medicine the growing neglect of which in this country is a matter of some reproach to the medical profession. In 1878 he was appointed co-lecturer, having as his colleague the late Mr. Somers, in materia medica and therapeutics at Owens College, and on the death of Mr. Somers five years later he became sole lecturer, being at the same time appointed professor of materia medica and therapeutics, which post he held till his death. Upon the appointment of Dr. Leech to the chair Owens College possessed no Materia Medica Museum and to supply this want, which he felt to be fatal to good and fruitful teaching, he set himself with zeal. He spared no trouble and no expense (for the calls upon his private purse in behalf of the Materia Medica Museum were not small), and he formed one of the finest museums in the country, attached to which is a department of experimental pharmacology where excellent work has been done under his supervision and where the spirit of his teaching still remains as a stimulus to further exertion in pharmacological research.

If Dr. Leech had contributed nothing to the progress of medicine but his work in organising a Materia Medica Museum for Owens College and in delivering there his admirable scientific discourses upon pharmacology he would have deserved to be ranked among the prominent medical men of our day; but though pharmacology was Dr. Leech's especial bent he did not allow its study to keep him from a wide interpretation of the duties and responsibilities of a physician. In 1875 he was admitted a member of the Royal College of Physicians of London, a year later he took the degree of Doctor of Medicine of London University, and was elected a Fellow of the Royal College of Physicians of London in 1882. Three or four years previously to this he was elected full physician to Manchester Infirmary, which appointment he held for 21 years, only resigning it about a year ago when he was appointed consulting physician. Dr. Leech's career is, however, but half described when we say that he was an excellent hospital physician with a large private practice and was an admirable professor in the University College of Manchester. He had many other interests, and many other duties were laid upon him, and the way in which he discharged them earned him the gratitude of his fellow-citizens. Thirty years ago he became the secretary of the Manchester and Salford Sanitary Association which through Dr. Leech's powerful instrumentality has rendered the city of Manchester incalculable benefits. To it the corporation owe the institution of many wholesome by-laws, while its teachings have assisted the authorities in the most practical manner to prevent the terrible dangers that follow upon the adulteration of food and upon a vitiated milk-supply, while in particular to this association belongs the honour of being the first body vigorously to combat the evils of black smoke. Several of Dr. Leech's reports upon this subject and upon the pollution of rivers were of the greatest value to the community.

Owens College, Manchester, is much beholden to its dead professor. He was a member of the Council and of the Court of Governors and played an important part in the organisation of the medical faculty of Victoria University. When the University was established Dr. Leech was appointed Chairman of Convocation and Representative of the University upon the General Medical Council, and his services in these two capacities the University acknowledged four years ago by granting him the degree of D.Sc.

Among the many complex problems of medicine few are more interesting than those connected with the accurate determination of the methods of action of particular groups of drugs which possess definite chemical affinities, and all pharmacologists owe the late professor of materia medica and therapeutics at Manchester a real debt of gratitude for his earnest endeavours to increase our knowledge in this direction. In 1893 Dr. Leech took as his subject for the Croonian Lectures before the Royal College of Physicians of London the Pharmacological Action and Therapeutic Uses of the Nitrites and Allied Compounds.[1] In tracing the physiological influence of groups of elements, more particularly of the groups formed by oxygen and nitrogen, he gave in the first two lectures a summary of his own work and proved it to be of considerable practical importance as well as most thoroughly and conscientiously executed. He desired his hearers to obtain a more intelligent appreciation of the conditions of efficiency of the nitrites as a group, and with this object he not only detailed his own experiments but reviewed those of Sir T. Lauder Brunton, Professor Cash, Dr. Filehne, Dr. Reichert, and the late Sir B. W. Richardson in a way that was remarkably intelligible considering the difficulty of the subject. In the last two lectures he dealt mainly with the therapeutic value of the remedies falling under these groups and his conclusions were valuable because of the scrupulous way in which they had been arrived at. Many busy practitioners who looked askance

[1] THE LANCET, June 24th (p. 1499) and July 1st (p. 3), 8th (p. 76), 15th (p. 123), and 22nd (p. 177), 1893.

when these lectures were published in our columns at the unfamiliar names of the drugs mentioned perceived the value of Dr. Leech's work when he proceeded to apply his theories to the estimation of the dosage of such therapeutic agents as nitrite of amyl and ethyl to many common conditions and to give his reason for his teachings.

Dr. Leech will nowhere be more missed and regretted than in the General Medical Council, where he represented the Victoria University. He was, in truth, one of the most useful members of the Council. He was elected to it in 1891 and took an active part in various committees. Of late he had been chiefly occupied in the work of the Pharmacopœia Committee, where the practical and scientific knowledge of drugs to which we have just alluded was of the greatest use to the counsels of the body that has charge of the issue of the British Pharmacopœia. On the death of Sir Richard Quain he was made chairman of the committee, and to him is due much of the credit which has been universally given to the work. He did not speak long or frequently in the Council, but whenever he did speak his views carried much weight. He was especially interested in all questions affecting the general practitioner, such as the various Midwives Bills, the abolition of the unqualified assistant, and the institution of a Conciliation Board to attempt to settle some of the points at issue between the medical profession and friendly societies and medical aid associations. He was a member of the first committee on medical aid associations in 1893 and gave the closest attention to the subject. Up to the last his interest in the work of the Council continued, especially in all questions relating to the Pharmacopeia, and he sent to the Council at the May meeting, through Dr. Donald MacAlister, touching expressions of this interest and left to it several valuable works on pharmacy and materia medica.

Dr. Leech took a prominent part in the affairs of the British Medical Association, being joint general secretary with Dr. C. J. Cullingworth and Mr. James Hardie when the Association met at Manchester, President in 1890 of the Lancashire and Cheshire Branch, and President of the Section of Pharmacology when the Association met at Montreal. He was also a ruling spirit and a late President of the Manchester Medical Society and founder of the Manchester Therapeutical Society, a young and earnest scientific body working on the lines of research where he had made himself a pioneer. He was for several years editor of the *Medical Chronicle*, and the pages of our Manchester contemporary contain many contributions from his pen. He was also a magistrate for the city.

We have said enough to show that in Dr. Leech Manchester has lost a citizen and medicine a representative which both must deeply regret. An excellent physician, a sound teacher, and an original worker Dr. Leech joined to his high intellectual qualities a particularly charming nature. He was kind, generous, and fair-minded, prudent in counsel, and while leaning to the weaker side was never afraid to speak his mind. All his work, whether public, medical, or strictly scientific, had one aim—the good of his generation. He bore his last illness with fortitude and leaves behind him many friends to recall his good qualities.

Dr. Leech married the daughter of Mr. Maclaren of Whalley Range, who survives him.

HENRY EWBANK, M.R.C.S. ENG., L.R.C.P. EDIN.

A WIDE circle of friends and acquaintances will hear with deep regret of the death after a long and painful illness of Mr. Henry Ewbank, at his residence, 5, Berkeley-place, Cheltenham. The deceased gentleman was a native of St. Germains, Cornwall, and was only 44 years of age. He received his medical training at University College Hospital, London and he went to Cheltenham some 20 years ago to begin his professional career as junior house surgeon of the General Hospital. His stay there was short but eminently successful. In 1881 he succeeded Dr. Cardew as senior surgeon; and on his resignation in May, 1883, he was presented with a case of instruments by the staff, by whom his departure was generally regretted. He left the hospital to enter into partnership with Dr. Gooding of Cheltenham, with whom he was long and honourably associated. The partnership was dissolved in 1895. For a short interval he practised on his own account; but about two years ago he was joined in partnership by his relative, Mr. C. Ewbank Lansdown. He was formerly honorary surgeon to the Home for Sick Children. Much of his popularity was due to the interest which he took in all forms of outdoor sport and to his genial good comradeship with sportsmen of all classes. In his young days he greatly excelled as a swimmer, and he was at one time looked upon as the leading amateur in the West of England. In fact, he enjoyed the unusual honour of having inflicted defeat on the great Captain Webb himself in a quarter-mile race at Westminster. Nor was that the only occasion on which he met the world-famed swimmer in friendly contest, as he was defeated by the champion in a half-mile race at the Cheltenham Montpelier Baths. For some time he was chairman of the Cheltenham Swimming Club and ably presided over the business meetings and social gatherings. He was a consistent supporter of cricket, football, and similar clubs, and he has done good work on the committee of the Cheltenham Cricket Club, having also from time to time undertaken the captaincy of the second eleven. In 1890 he married Mary Elizabeth, eldest daughter of the late Martin Inett Preston, solicitor, of Nottingham. He leaves a widow and two children.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Fritz Rubenstein of Berlin, who has made a reputation for himself in the domain of surgery and the use of the Roentgen rays as well as by his writings on philosophical and literary topics, has died from the effects of a poisoned wound, at the age of 37 years.—Dr. H. Benedikt, son of the Vienna professor, who has published various researches on radiography.—Dr. F. Nott Otis, formerly Professor of Genito-urinary Diseases in the College of Physicians and Surgeons, New York.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in the subjects indicated.

Wednesday, July 4th:

Anatomy and Physiology.—Robert Mackenzie im Thurn and Arthur Hallowes, St. Bartholomew's Hospital; John Speechly Le Fevre, Samuel Smulian, George Delaval Walsh, and George Meredith Sanderson, London Hospital; Reginald Henry Hardwick and Thomas Andrew Chater, St. Thomas's Hospital; James Matthew O'Brien, Geoffry Smyth Oades, and John Bourdas, Charing Cross Hospital; Ernest Harrison Griffin, Cambridge University and Guy's Hospital; Percy Claude Vincent Bent, Herbert Douglas Smart, and Edgar Norman Jupp, Guy's Hospital; George Christian Blake Miéville, University College, London; Bertram Maughan Footner and William Joseph Edward Stuttaford, King's College, London; Frederic Rosenberg Harris and George Rowland Henderson Crozier, St. Mary's Hospital; and Charles Aubrey Godson, Hugh Basil Drake, and Leonard Erasmus Ellis, St. George's Hospital.

13 gentlemen were referred to their professional studies for three months.

Thursday, July 5th:

Anatomy and Physiology.—Bernard Beryl Riviere, Lauriston Leonard Winterbotham, Alan Hargrave Pinder, and Kenelm Digby Bell, St. Bartholomew's Hospital; Harold Harris Elborough Scatliff and Lionel Danyers Bailey, St. George's Hospital; Charles Herbert Romer Coltart, Westminster Hospital; William Percival Hingston and Peter Gifford Foulkes, Middlesex Hospital; Charles Robert Shattock, Frank Percival Hughes, Charles Frederick Fraser, and Francis William Fawssett, Guy's Hospital; George Russell Rew, Cyril Thomas Cheatle, and John Henry Napper, King's College, London; William George Cheatle and Russell Edwards Palmer, St. Mary's Hospital; Austin Clarence Dixon, James Stewart, and Edward John Henry Rudge, London Hospital; Harry Morgan Gilmour and Augustine Henry Hudson, St. Thomas's Hospital; James Vere Arkle, University of New Zealand and St. Thomas's Hospital; and George Archibald Bosson, University College, London.

Anatomy only.—Samuel Goodman, St. Thomas's Hospital.

Physiology only.—Clifford Greville Simms, Middlesex Hospital; Joseph Wilding, St. Bartholomew's Hospital; and Ernest John Hamilton Bowen, University College, Cardiff, and King's College, London.

Eight gentlemen were referred in both subjects, two in Anatomy only and two in Physiology only.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination held in July the following candidates passed in the subjects indicated:—

PART I.

Biology.—C. H. Osmond, Glasgow.

Chemistry.—A. G. Gamble, Leeds; J. E. Jones, Bristol; and O. F. W. Steele, Birmingham.
Materia Medica and Pharmacy.—B. F. Board, M. Foley, E. M. Handley, C. Kellgren, and A. M. Marval, Royal Free Hospital; J. E. Mondon, Glasgow; O. P. N. Pearn, Westminster Hospital; and E. Renouf, Royal Free Hospital.

PART II.

Anatomy.—J. J. Anning, Leeds; W. H. Bush, Guy's Hospital; D. Cotes-Preedy, Cambridge and St. George's Hospital; W. L. Crabtree, Leeds; J. Cretin, Bristol; I. Griffith, London Hospital; E. W. Hutton, St. Thomas's and Westminster Hospitals; H. A. Parker, St. Thomas's Hospital; W. W. Read, Guy's Hospital; Z. Rowlands and E. Serjeant, Royal Free Hospital; J. P. B. Snell, Middlesex Hospital; A. W. D. Thomson, St. George's Hospital; and E. N. L. Wilson, Royal Free Hospital.
Physiology.—J. J. Anning, Leeds; F. D. S. Barker, Royal Free Hospital; D. Cotes-Preedy, Cambridge and St. George's Hospital; J. Cretin, Bristol; E. W. Hutton, St. Thomas's and Westminster Hospitals; H. Johnson, Guy's Hospital; A. R. McEnnery, Bristol; W. W. Read, Guy's Hospital; Z. Rowlands and E. Serjeant, Royal Free Hospital; J. P. B. Snell, Middlesex Hospital; W. P. Taylor, Sheffield and Bristol; A. W. D. Thomson, St. George's Hospital; and E. N. L. Wilson, Royal Free Hospital.

A DAY OF REST FOR THE METROPOLITAN NURSES.—On Wednesday, June 27th, the nurses of the London hospitals and metropolitan nursing institutions spent a day in the country at Hertingfordbury. Advantage was taken of the occasion to help those who were present to realise in devotional exercise the spiritual character and dignity of the nurse's vocation as an essential part of the Christian ministry. The "Day" commenced with a celebration of the Holy Communion in the parish church. The Very Rev. the Dean of Windsor gave the address, taking for his text, "Rest in the Lord." Evening prayer was said by the rector at 3.30, the dean again giving the address, based upon the Psalmist's words, "Delight thyself in the Lord." Dinner and tea were provided, and by the kindness of the Earl and Countess Cowper the visitors were invited to inspect the picture-gallery at Panshanger.

WEST-LONDON MEDICO-CHIRURGICAL SOCIETY.—The following gentlemen have been elected as officers and members of council for 1900-1901. President: Dr. F. F. Schacht. Vice-Presidents: Dr. Seymour Taylor, Mr. Neville T. Wood, Dr. F. J. McCann, Dr. F. H. Low, Mr. C. Andrews, Dr. J. A. Coutts, Dr. J. Crombie, and Dr. S. A. Bontor. Council: Mr. F. R. Mallard, Mr. F. Savery, Mr. E. Bartlett, Dr. D. R. Pearson, Mr. G. E. Twynam, Mr. H. W. Chambers, Dr. G. D. Robinson, Mr. H. Webb, Dr. T. R. Atkinson, Mr. W. S. Fincham, Dr. A. Baldock, and Mr. M. H. Taylor. Treasurer: Mr. T. Gunton Alderton. Secretaries: Dr. G. P. Shuter and Dr. Leonard Dobson. Librarian: Mr. C. B. Keetley. Editor of Journal: Mr. H. Percy Dunn. Editorial Secretary of Journal: Mr. McAdam Eccles.

EPSOM COLLEGE.—The following are the results of recent examinations for entrance scholarships and exhibitions:—Scholarships and Council Exhibitioners: Elected to Senior Scholarships: A. Master and A. C. C. Parkinson. Elected to Junior Scholarships: C. E. Milner and A. Ll. Jones. Elected to Entrance Scholarships: G. T. Vivian (Messrs. Clarke and Crouch, Seaford), D. Rahilly (Fairleigh School, Weston-super-Mare), E. A. C. Fazan (Rose Hill School, Tunbridge Wells), and E. L. M. Emtage (private tuition). Elected to Council Exhibitions: R. Nankivell and J. H. A. Hynes.

THE WATER-SUPPLY OF BARRY, SOUTH WALES.—Owing to the rapid increase of the population of Barry the local authority last year decided to increase the water-supply by sinking another well at Biglis. The works are nearly completed and will increase the pumping capacity at Biglis from 500,000 gallons of water per day to more than twice that quantity. The cost has been about £6000.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.—At a meeting of the Governing Board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary, Mr. R. N. Ramsay, reported that the number of students attending the school during this session was 1109.

MEDICAL MAGISTRATES.—Mr. J. Whitehead Bentley, L.R.C.P.Edin., M.R.C.S.Eng., of Stockport, and Mr. James Bernard Wall, L.R.C.P., L.R.C.S. Edin., of Coleshill, Warwickshire, have been appointed magistrates for the boroughs of Stockport and Coleshill respectively.

ON July 4th the new wards at the Devonport Workhouse Infirmary, erected at an outlay of £4000, were formally opened.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—We are asked to state that Licentiates of the College who desire to claim the advantage of the concession for the Fellowship, in recognition of the Royal visit, should apply before July 31st, 1900.

MR. WILLIAM H. CORFIELD, M.D. Oxon., F.R.C.P. Lond., Professor of Hygiene and Public Health, University College, London, has been elected a Foreign Corresponding Member of the Royal Academy of Medicine of Belgium.

IN MEMORIAM.—The treasurer of Queen's Hospital, Birmingham, has received a cheque for £1250 from Mrs. Poncia, Gough-road, Edgbaston, for the endowment of a bed in memory of her husband, the late Mr. John Poncia.

MR. PRIESTLEY SMITH, M.R.C.S. Eng., of Birmingham, has been elected as representative of the Faculty of Medicine on the council of the Birmingham University.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Proposed Extension of the Medical Act of 1858.

ON Friday, July 20th, General LAURIE, Member for Pembroke and Haverfordwest, will introduce a Bill into the House of Commons to extend the provisions of the Medical Act of 1858. The Bill is the outcome of the refusal of the War Office to accept the services of Canadian militia medical officers in the field in South Africa. In the first case brought to the knowledge of General Laurie, the surgeon of Montreal General Hospital, who also holds a commission as surgeon in one of the local militia regiments, was refused on the ground that it would be contrary to law to employ in the military service a medical man who was not registered under the Medical Act of 1858. Subsequently the Canadian Government offered a complete field hospital and it was refused on the same ground. General Laurie considers that the remedy for this state of things lies in a recognition in the Medical Acts of schools of medicine throughout the Empire which are recognised by their respective Governments and whose requirements come up to the standard established and maintained by the General Medical Council. This is what he proposes to do in his Bill.

HOUSE OF COMMONS.

TUESDAY, JULY 3RD.

The Inspection of Irish Hospitals.

Mr. PATRICK O'BRIEN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that union general hospitals and union fever hospitals in Ireland were inspected and reported upon by lay inspectors, and could he state what qualifications these gentlemen possessed for the discharge of this duty; was he aware that the Irish Workhouse Reform Association and the Irish Medical Association recommended that those hospitals should be inspected by professional men; and would he see that effect was given to those recommendations?—Mr. GERALD BALFOUR replied: The inspection of workhouses in Ireland, as in England, is under the general inspectors who report on the state of the buildings, the cleanliness, order, discipline, the keeping of the books, the finance, and the compliance with the general regulations by the several officers in every department, including the hospital wards. It would not be practicable to exclude these wards from the general inspectors' authority, but when any questions as to medical treatment arise, or where any inquiry has to be held wherein medical knowledge is required, a medical inspector makes a special inspection or holds any inquiry on oath that may be necessary. The question of assigning this work to a special medical inspector appointed for the purpose is under consideration.

Hospital Staff at Shorncliffe Camp.

Captain NORTON asked the Under Secretary of State for War if he was aware that at an inquest held on Saturday last at Shorncliffe Camp on Sergeant Wilmshurst, of the Sussex Regiment, it was shown in evidence that there was not a single orderly of the Army Medical Corps in the hospital, and that Wilmshurst, when taken to the hospital in a fit, died before a doctor could be found; and in view of the comments made by the jury at the inquest whether he could say what steps, if any, were now being taken to secure without delay an adequate staff for our military hospitals both at home and abroad.—Mr. WYNDHAM replied: No information has been received in the War Office of this incident, but inquiry will be made. The staff of the hospital consists of a sergeant-major, a sergeant, two corporals, and 14 orderlies of the Army Medical Corps, besides regimental soldiers.

Widal's Method of Diagnosis.

Dr. FARQUHARSON asked the Under Secretary of State for War whether he would state what steps were taken by the War Office to provide means for the application of the serum test (Widal's method) to the diagnosis of doubtful cases of enteric fever in general hospitals in South Africa, whether he was aware that this means of making an early diagnosis was largely used by hospitals and local sanitary authorities,

and whether he would take immediate steps to provide every general hospital in South Africa with the skilled assistance and simple appliances necessary in these cases in which such provision had not yet been made?—Mr. WYNDHAM replied: No special steps have been taken beyond the general training of medical officers in this method of diagnosis. The test is being applied in South Africa and army medical officers are quite capable of carrying it out.

THURSDAY, JULY 5TH.

Volunteer Surgeons in Camp.

Sir HOWARD VINCENT asked the Under Secretary of State for War if a decision had yet been taken to facilitate the attendance of volunteer surgeons in camp and to enable the pay and allowances of one surgeon to be divided according to the attendance their private practice enabled them to give.—Mr. WYNDHAM replied: Yes, sir; the Secretary of State has decided to make this concession to the medical officers of volunteer corps.

Death under Anæsthetics.

Mr. MACALEESE asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could give any particulars to the House regarding the case of a man named George Dover who died at the Belfast Royal Hospital on June 7th under an anæsthetic, and would he explain why no inquest was held in this case to ascertain if the anæsthetic which proved fatal had been properly administered, while on the same day an inquest was held on another hospital case in which the jury returned a verdict of death from natural causes; was he aware that the town clerk of Belfast, at the instance of the Finance Committee of the City Council, asked for an explanation of this matter from the coroner who replied that the only person entitled to demand explanations from him was the Lord Chancellor; and would he take steps to draw the attention of the Lord Chancellor to this case?—Mr. GERALD BALFOUR replied: I understand that the coroner, in the exercise of the discretion vested in him, decided that it was unnecessary to hold an inquest in the case of George Dover, whilst in the second case referred to he found it imperatively necessary to hold an inquest. It is open to any of the parties interested to bring the action of the coroner under the notice of the Lord Chancellor. He is not an officer of the Executive, and the Government see no reason for intervening as suggested in the last paragraph of the question.

Hospital Orderlies in South Africa.

In reply to a question on this subject addressed to him by Sir WALTER FOSTER Mr. WYNDHAM said: The number of hospital orderlies employed in South Africa were as follows:—March 17th, 2936, including 560 St. John Ambulance Brigade; April 21st, 3739, including 766 St. John Ambulance Brigade, 84 Militia Medical Staff Corps, and 361 Volunteers; May 19th, 3943, including 986 St. John Ambulance Brigade, 91 Militia Medical Staff Corps, and 492 Volunteers. This does not include the staff of such hospitals as the Yeomanry Hospital, Portland Hospital, &c., the subordinate male staff of which numbers 519, but of which it is not known how many are employed as orderlies. The returns of medical staff raised locally in addition to the above are not furnished to the War Office, but 1200 stretcher bearers are known to have been raised in Natal, thereby releasing orderlies of the Royal Army Medical Corps for duty in the hospitals.

The Treatment of the Sick and Wounded in South Africa.

Mr. BALFOUR announced that it was proposed to appoint a commission consisting of Dr. Church, President of the Royal College of Physicians of London; Dr. Daniel John Cunningham, Professor of Anatomy and Surgery in Trinity College, Dublin; and Lord Justice Romer, to report on the arrangements for the care and treatment of the sick and wounded during the South African campaign.—Mr. DILLON asked whether the Government would appoint an independent commission to inquire as to the responsibility of the War Office in connexion with the treatment of the sick and wounded in South Africa and into the organisation and present condition of the Army Medical Department, such commission to sit immediately and conduct its inquiry independently of the commission which it is proposed to send to South Africa.—Mr. BALFOUR replied that two independent and simultaneous commissions whose duties would overlap seemed to him to be very objectionable.

Later in the day there was a long debate on the composition of, and the scope of the reference to, the proposed commission. Many members expressed a strong desire to have the terms of reference extended and the number of commissioners enlarged and some took exception to medical men having a preponderating voice in an inquiry where questions of transport and military organisation were so largely involved and in connexion with which there had been an attack upon the Army Medical Department. At the close of the debate Mr. BALFOUR, while insisting on the superiority of the Government proposal and saying that in his opinion the House was wrong, said he must yield to the opinions expressed and do his best to consult with his colleagues as to how they could increase the number of commissioners from three to five. He declined, however, to enlarge the scope of the reference.

FRIDAY, JULY 6TH.

Uncertified Deaths in Scotland.

In Committee of Supply on the Scottish Estimates Mr. WEIR and Sir CHARLES CAMERON called attention to the large number of uncertified deaths in the Highlands and others of the remoter parts of Scotland. The latter suggested that in his return the Registrar-General should record separately the certified and the uncertified deaths, so that it might be seen whether any progress was being made in the matter of certification. He reminded the House that the Select Committee of a few years ago found that in some of the western parts of Scotland 50 per cent. of the deaths were uncertified by a medical man and that in spite of this state of things the recommendations of the Committee had not been carried into effect.—The LORD ADVOCATE, by way of reply, said he would place Sir Charles Cameron's suggestion before the Registrar-General.—Mr. WEIR protested against this reply as altogether inadequate and unsatisfactory. In his own constituency of Ross and Cromarty there were hundreds of uncertified deaths every year—a state of things which he regarded as a public scandal. By way of emphasising his protest Mr. WEIR moved a reduction in the vote under the review.

The Use of Glycerinated Calf Lymph in Scotland.

On the vote for the Local Government Board for Scotland Sir CHARLES CAMERON drew attention to the small proportion of glycerinated calf lymph distributed in Scotland as compared with the proportion distributed in England.—The LORD ADVOCATE replied that up to the present the advantages of the lymph had not been brought home to the people so clearly in Scotland as in England. He was glad, however, to be able to assure the hon. member that the demand for it was steadily increasing, and he thought the hon. member and others interested might feel certain that this steady increase would be maintained.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ABERCROMBIE, PETER H., M.D., C.M., has been appointed Assistant Surgeon to the Central London Throat and Ear Hospital, Gray's Inn-road, W.C.

ASTIN, WILSON, M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Loughton Urban District.

BARFORD, ARTHUR, M.D., has been appointed Assistant Anæsthetist to the Central London Throat and Ear Hospital, Gray's Inn-road, W.C.

BEAUMONT, A. W., B.A. Camb., M.D. Dubl., has been re-appointed Medical Officer of Health by the East Ham Urban Council.

BELLAMY, J. H., junr., L.R.C.P. Lond., M.R.C.S., has been appointed Senior Resident Medical Officer at the Workhouse by the Sheffield Board of Guardians.

BROWNE, G. H., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Blaina Sanitary District of the Tredegar Union.

BURGESS, G., M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Great Driffield Urban Sanitary District, vice R. Wood, resigned.

GOLDSMITH, G. H., M.B. Cantab., has been appointed Medical Officer to the Bedford Union Workhouse.

GRAY, W. G., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Holsworthy Urban Sanitary District.

HOWELLS, W., M.B., C.M. Glasg., has been appointed Medical Officer of the Workhouse, Brecknock Union, vice W. M. Parham, resigned.

HULBERT, E. B., M.D. Durh., M.R.C.S., L.R.C.P., has been appointed Second Assistant Medical Officer to the St. Marylebone Infirmary, North Kensington, W., vice E. Worley, resigned.

HUTCHENS, H. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Superintendent of the Plague Hospital, Brisbane, Queensland.

LEONARD, NORMAN, has been appointed Analyst for the Borough of Northampton, vice Messrs. Swete and Ross.

MCFARLAND, B., M.D., M.Ch. Irel., has been re-appointed Medical Officer for the Lincoln Workhouse.

MCWALTER, J. C., L.R.C.P., L.R.C.S. Irel., has been elected a Fellow of the Royal Institute of Public Health.

MORICE, C. G. F., M.D. Brux., F.R.C.S. Eng., has been appointed Sanitary Commissioner for Westland and Buller, New Zealand.

NOURSE, W. J. C., F.R.C.S. Edin., has been appointed Assistant Surgeon to the Central London Throat and Ear Hospital, Gray's Inn-road, W.C.

PECK, H., M.D. Edin., D.P.H. Camb., has been re-appointed Medical Officer of Health by the Chesterfield Town Council.

PLATT, J. E., M.S. Lond., F.R.C.S. has been appointed Honorary Assistant Surgeon to the Manchester Royal Infirmary.

WEAVER, J. J., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Southport, vice H. H. Vernon, deceased.

WEBSTER, F. J., M.R.C.S., has been appointed Medical Officer of Health for the Vaynor and Penderyn Rural Sanitary District, vice T. J. Dyke, deceased.

WEIGHTMAN, E. J., M.B., C.M. Edin., has been appointed Medical Officer of the Workhouse and Children's Homes, Middlesbrough Union, vice L. G. Davies, resigned.

WILLIAMS, W. R. E., M.B., M.R.C.S., has been appointed Assistant Resident Medical Officer to the Mill-road Infirmary, Liverpool.

WHITAKER, E. T., M.B., C.M. Edin., B.Sc., D.P.H. Camb., has been appointed Medical Officer of Health for the Wem Urban Sanitary District.

WOODFORD, E. V. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 1 Sanitary District and the Workhouse of the Abingdon Union.

WYNNE, WALTER, M.B., C.M. Edin., has been appointed Medical Officer of Health by the Rye Rural District Council.

Vacancies.

For further information regarding each vacancy reference should made to the advertisement (see Index).

ALTON CAMP. — HOSPITAL AND CONVALESCENT CAMP FOR SICK, WOUNDED, AND CONVALESCENT SOLDIERS (now in course of erection). —Positions on the Medical and Surgical Staff. Applications in the first instance by post, addressed Manager, Absent-minded Beggar Relief Corps, Room 44, Harmsworth-buildings, Tallis-street, London, E.C.

BEDFORD COUNTY HOSPITAL.—Assistant House Physician. Salary £25 for six months, with board, lodging, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—Assistant House Surgeon. Salary £60 per annum, with apartments and board.

BOROUGH OF BOOTLE HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Superintendent, unmarried. Salary £120 per annum, with board, washing, and apartments at the hospital. Apply to the Chairman of the Health Committee, Town Hall, Bootle.

BRADFORD ROYAL INFIRMARY.—House Physician for 12 months, unmarried. Salary £100 per annum, with board and residence.

BRECON INFIRMARY, No. 6, Bulwark, Brecon, South Wales.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas.

BRISTOL EYE HOSPITAL.—Locum Tenens for the House Surgeon for two months. Salary 2½ guineas a week, without residence.

CARDIFF INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.

CARLISLE DISPENSARY (not provident).—House Surgeon. Salary £150 per annum, with apartments (not board).

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Annual re-appointment, but tenable for three years. Honorarium 20 guineas per annum.

CHESTER GENERAL INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with residence and maintenance in the house.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising £10 annually to £150, with board, furnished apartments, &c. Also Locum Tenens for one month or more. Terms £3 3s. and all found, with second-class return fare.

CORPORATION OF BIRMINGHAM—CITY HOSPITAL, Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary commences at £125 per annum, with furnished apartments, board, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

AUDEN.—On July 5th, at Bootham, York, Constance, the wife of George A. Auden, M.A., M.D. Cantab., of a son.

DONALD.—On July 4th, at Platt Abbey, Rusholme, Manchester, the wife of Archibald Donald, M.D., of a daughter.

FACEY.—On July 7th, at The Lodge, Maldon, Essex, the wife of W. E. Facey, B.A., M.B. Cantab., of a son.

GUTHRIE.—On July 2nd, at Belmont, Tunbridge Wells, the wife of T. C. Guthrie, M.B., of a son.

MILLS.—On July 6th, at Hill-street, Haverfordwest, the wife of Yarnold Mills, M.B. Lond., F.R.C.S. Eng., of a daughter.

WARD.—On July 9th, at Museum-street, Ipswich, the wife of Francis Ward, M.D., of a son.

WHITFIELD.—On July 6th, at Upper Berkeley-street, W., the wife of Arthur Whitfield, M.D., M.R.C.P., of a daughter.

MARRIAGES.

ADDISON—MOTTRAM.—On July 6th, at St. Bartholomew's, Norwich, Eldred Arthur Addison, M.R.C.S., L.R.C.P., of Coddenham, Suffolk, to Marion Watson, younger daughter of Alfred Mottram, Heigham Hall, Norwich.

BIRLEY—STOWELL.—On July 5th, at the parish church, Chorley, Hugh Kennedy Birley, M.D., of Weaste, Manchester, to Ellin Cecilia Stowell.

DOWDEN—KERANS.—On July 9th, at St. John's, Paddington, Richard Dowden, M.D., to Jessie Allen Kerans, second daughter of T. G. Kerans, of Southwick-place, Hyde-park-square, London.

WHITE—FRASER.—On July 3rd, at St. Michael's Church, Blackheath-park, Finch White, M.R.C.S., L.R.C.P., son of Colonel Finch White, late 85th Light Infantry, to Annie Violet, second daughter of the late James Fraser, of Newfield, Blackheath-park, S.E.

DEATHS.

HOWARD.—On June 22nd, at Elberon, New Jersey, Benjamin D. Howard, M.A., M.D., M.R.C.S., F.R.C.S.E., of New York, aged 64 years.

JAMES.—On July 9th, at 62, Comeragh-road, West Kensington, Henry James, formerly of Weybridge, Surrey, F.R.C.S., aged 83 years. No flowers by desire.

SQUIRE.—On July 6th, at Maitland-park-villas, Haverstock-hill, N.W., Robert Hemington Squire, B.A., M.R.C.S., aged 57 years.

STEELE.—On the 10th inst., at 33, Via S. Gallo, Florence, after seven years' painful illness unmurmuringly borne, Sarah Louisa, wife of J. P. Steele, B.A., M.D. Edin., and younger daughter of the late Rev. William and Lady Louisa Augusta Anne le Poer Trench.

WATERHOUSE.—On July 10th, at his residence, Croxteth-grove, Sefton-park, Liverpool, Charles Henry Waterhouse, M.D.

N.B. A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE HONOUR AND DIGNITY OF THE MEDICAL PROFESSION."

OUR correspondent whose letter we printed last week thus continues his jeremiad:—

"Shall I turn to our great hospitals for relief from this intolerable monotony of unwholesome competition which is disastrous in the long run not only for our profession but also for the public? The other day I heard of a tradesman of undoubted veracity in the City of London who was advised to see a distinguished dentist at the West-end who holds the appointment of dental surgeon to one of our large medical schools in London. The fee which this dentist demanded was 30 guineas. When the patient said that this fee was rather more than he expected the dentist at once replied, 'Well, if you do not mind going to *my* hospital *my* assistant will extract five of your teeth, this will save five guineas and reduce my fee to 25 guineas only.' This incident, for which I can vouch, leads me to ask a few more questions. Why should the junior staff of our hospitals work for nothing and their seniors take the credit, and what is more the pay as well, if any? Why should the General Medical Council adjudicate that a medical man who covers an unqualified assistant at a midwifery case is guilty of infamous conduct in a professional respect, although he may be well aware of the abilities of his assistant, as well as being morally, legally, and pecuniarily responsible for the management and result of the case, and then immediately afterwards stultify themselves by bolstering up a Bill to make midwifery conducted by a nurse a legal act? Will a medical man be judged guilty of infamous conduct who covers one of these legal Gamps? Why should the Council of the Royal Colleges of Physicians and Surgeons support the Midwives Bill after selling their diplomas and licences to their members and licentiates and promising to protect them? Most of the censors of the Royal College of Physicians of London do not attend any midwifery and the members of the Council of the Royal College of Surgeons of England especially are debarred from attending any by the tenure of their office as surgeons to the large hospitals. Therefore what can these know of the requirements of the public or the profession so far as midwifery is concerned? Why should the just rights of the juniors in the profession be undermined and bartered away by their seniors? Why do not the heads of our profession constitute themselves as special examining bodies of chiropodists, manicurists, masseurs, and the like? Why do we find the names of medical men on the self-constituted boards of examiners of spectacle-makers, plumbers, &c.? We shall soon have them examiners of the colleges of boot and shoemakers, sanitary clothiers, and wooden leg makers, and this, too, with quite as much reason. Quite recently there has been an appointment of parish infirmary doctor offered for competition to women. There were some dozen candidates for the appointment at the munificent wages of less than £2 a week. Some of these women a few years ago pleaded that they wanted to enter the medical profession in order to attend their suffering sisters out in India. Does this wholesale competition amongst themselves for an appointment to attend paupers in London prove that the way to India is through the workhouse? Why should a medical man or woman accept less remuneration than a professional nurse, or the quill-driver who wrote out the advertisement, or the compositor who sets up the type, less almost than the very printer's devil, now almost extinct, who applies the necessary ink. I was dining out a short time ago when one of the guests said that he had to attend upon a jury, and this was exceedingly annoying and inconvenient, when another guest who did not know me intimately said: 'Why not get a medical certificate?' at the same time adding, '*Any* doctor will give you one for a shilling!' Shall we sigh and say, 'Alack and alas! is it not true?'"

AXIS TRACTION FORCEPS.

To the Editors of THE LANCET.

SIRS,—Would you, or some of your readers, oblige me by advising me as to the best form of axis traction forceps to purchase? Is there any real advantage in having Neville's arrangement attached to the ordinary Barnes-Simpson?

I am, Sirs, yours faithfully,

July 11th, 1900. A COUNTRY SURGEON.

RAILWAY SANITARY ARRANGEMENTS.

A CORRESPONDENT writes:—"Are the water-closet and lavatory arrangements of corridor trains in the interests of public health? It seems to me that they are not. I have to-day travelled 250 odd miles in one such train, not overcrowded, and I had opportunity of noting that from one carriage alone that the visits to the lavatory were numerous, and some were made while the train was at a standstill in important stations. At the end of the journey myself and fellow-passengers, as is generally the case in summer, were very dusty. This dust was from the permanent way and carriage-fittings, I assume, as in this case the water-closet is usually open to deliver direct on to the ground. Thus the permanent way has become a receptacle for years past of human excrement which goes straight on to the line except so much as is driven by the impetus of the wind from the speed of the train on to its under-floor fittings, &c. I strongly suspect, if my surmise is right as to the general absence of receptacles, that if the under-floors, bearers, and wheels of the carriage were submitted to a careful examination they would reveal revelling myriads of microbes ready for revenge. Just fancy the scores of corridor trains which fly over our main trunk lines every day and the hundreds of people in all conditions of health, or otherwise, who use this modern 'convenience.' Surely the permanent ways, even in the stations, and certainly along the whole course of the line must be seething bacterial beds. It occurs to me that some arrangement might be made which, while meeting the needs of long-journey passengers in fast trains, might prevent this broadcast sowing of filth and disease. It is not as though the permanent way were subject to the influence of the plough on a friable soil, but this bacterial distribution falls on to hard rubble to be nourished by the sun and distributed by the wind. It would be an interesting inquiry whether platelayers, &c., and those who dwell in the immediate proximity of railways have any special record in the matter of disease. I may be quite wrong in my assumption that the absence of receptacles is general, and that if so there is death in the carriages. I think, however, you would contribute to the solution of what seems to me a most important national sanitary question if you would open your columns to the discussion of it."

WHO IS MR. W. HARTLEY AUSTIN?

Two correspondents write asking who is Mr. W. Hartley Austin, from whom they have received the following circular:—

93, Queen Victoria-street, London, E.C., 27th June, 1900.

DEAR SIR,—A large number of prominent gentlemen in your profession have recently been good enough to grant me a brief interview in order that I might explain an entirely new and most interesting investment, specially suitable for a medical man and guaranteed by a wealthy, old-established company with funds exceeding £2,000,000 sterling.

This investment is practically the *only* one under which you can take advantage of the extraordinary rapidity with which money accumulates at *compound* interest. You are, of course, aware that even a small sum will (if set aside each year and allowed to accumulate at *compound* interest) mount with great rapidity to a large total, while the ordinary investment at simple interest does not increase at all.

The investment I refer to enables you to set aside a moderate amount each year (from a £5 note upwards), to accumulate same at *compound* interest for a number of years, drawing the result either in cash or as a yearly addition to your income. Should you unfortunately *die* while the money is accumulating at compound interest your family or other dependents are provided for by life insurance *without further charge*.

I venture to ask if you also would grant me the favour of a few moments' conversation to bring this matter under your notice. If so, I feel confident you would be much interested in what I have to say, and I should not encroach in any way upon your valuable time.

Thanking you in anticipation of your returning the enclosed stamped postcard,

I am, yours faithfully,

W. HARTLEY AUSTIN.

The circular encloses a stamped card to be signed by the recipient when making appointments with Mr. Austin, who clearly saves his correspondents as much trouble as possible. We have not the least idea who Mr. Austin is. We do not follow his arguments with regard to the difference between simple and compound interest. Presumably, "most prominent gentlemen" in the medical profession know that money accumulating at compound interest increases more rapidly than money accumulating at simple interest; but no accumulation will take place under either system if all the interest is annually spent, while an "ordinary investment at simple interest" increases by the amount of that simple interest if the simple interest is not spent.

We recommend any of our readers who have received this circular to ask Mr. Austin for the usual banker's reference before entrusting him with money, if not before seeing him. An investment that is "guaranteed by a wealthy, old-established company with funds exceeding £2,000,000 sterling" should have no difficulty in furnishing undeniable credentials.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—"If they hear not Moses and the Prophets," &c., and so I say, if after all that has been advanced against the rule-of-thumb method of administration—no matter by whom the chloroform vapour be administered—then to say more is useless. Nearly every argument has been examined and good and sufficient reasons given by Dr. Edmunds for urging the adoption of the Krohne inhaler, and to designate such an exact method of administering chloroform vapour "the latest fad" in the face of such unanswerable evidence is a curious perversion of

the intellect. I am the last to deny the wonderful safety with which chloroform is administered by very many able men like Dr. Marshall, but the worst of it is that all who administer choloroform can hardly be classed in that list, otherwise we certainly should not have recorded the number of deaths that now unhappily obtain. Dr. Marshall may also be equally competent to dispense strychnine without measuring, but would he be justified in so doing? If not, how about the less competent? All I therefore venture to urge in connexion with this important question is that the safest mode of administering chloroform vapour should be worked out and adopted; that, in the hands of any ordinary practitioner with common sense, could hardly ever result in death. This, Sirs, I venture to think, in the absence of positive proof to the contrary, may be claimed for the "Krohne Inhaler, 1900."

Thanking Dr. Marshall for his reply,

I am, Sirs, yours faithfully,

C. J. HARRIS, M.R.C.S. Eng., &c.

Kilburn Priory, N.W., July 2nd, 1900.

A PROLIFIC FAMILY.

A PARAGRAPH in the June number of the *Maryland Medical Journal* states that among recent returns of births for the State of Maryland was a birth certificate sent by Dr. J. V. Wallace of Chesapeake City, who reported the birth on Feb. 23rd, 1900, of Warren O——. The grandmother and great-grandmother were present at the birth, while the great-great-grandmother was in a house in the neighbourhood. From this last-named lady, now only 72 years of age, there have sprung 11 children, of whom eight are living, and 50 grandchildren, of whom 18 are living. There are 22 great-grandchildren living, and there have been two great-great-grandchildren, one being the child Warren O——. The record does not give the number of great-grandchildren dead, but the figures given show that there have descended from this very superior mother 85 children, of whom 63 are living. The number of plural births is not given, but the oldest daughter, now 52 years old, had twins four times. This is a very remarkable record.

THE DUTIES OF A PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—As a subscriber to THE LANCET I shall be very glad if you will kindly answer the following question. I am a public vaccinator. Several persons in my district are summoned to appear before the magistrate for refusing to have their children vaccinated. I have subpœnas to attend the court and give evidence as to vaccination notices, &c. I want to know whether under the present Vaccination Act it does not come under the vaccination officer's duty to give all the evidence necessary to convict without the public vaccinator appearing in court. Also whether, in case I am bound to appear, I am entitled to a fee (half a guinea) for each case.

I am, Sirs, yours faithfully,

July 5th, 1900. X.

*** The duty of taking proceedings for the enforcement of the law devolves upon the vaccination officer. (See Schedule 4 of the Vaccination Act of 1898.) If, however, our correspondent has been subpœnaed he must attend. We should say that he is entitled to a fee for each case, but perhaps it would be as well for him to consult his legal adviser upon that point.—ED. L.

LIVING LARVÆ IN THE EAR.

To the Editors of THE LANCET.

SIRS,—The following, to myself at least, is an unusual experience and as a case of myiosis may be of interest. To-day a man consulted me with the history that some 10 hours previously he had been awakened from sleep by an unusual sensation in his left ear. He described it "as if he had wheels in his ear" and soon began to suffer pain and discomfort that increased to such an extent that he could bear it no longer and came to seek advice. On examining with a speculum and on inquiry I found that he had suffered many years from middle-ear disease. There were great swelling and inflammation of the tympanum and surrounding parts. On syringing out the ear with water I was astonished to see an animal some one-eighth of an inch in length make its appearance, and on further douching others of a like kind were washed out. I continued syringing till no more appeared and counted 14 larvæ, all alive. I finished syringing the ear with sol. hyd. perchlor., and the patient went away feeling quite relieved and free from pain. I presume these were the larvæ of a species of creophila.—I am, Sirs, yours faithfully,

D. J. DRAKE, M.R.C.S. Eng., L.R.C.P. Lond.,

June 21st, 1900. Medical Officer to the Ray Copper Co., Arizona.

BOOKS ON PHYSIOLOGICAL CHEMISTRY.

To the Editors of THE LANCET.

SIRS,—Will you kindly recommend a reliable work solely upon physiological chemistry? "A Text-book of Physiological Chemistry," by Olof Hammarsten, published for Wiley and Sons by Chapman and Hall, has been recommended. I am, Sirs, yours faithfully,

July 9th, 1900. STUDENT.

*** The book mentioned is a good one. Another admirable work is Halliburton's "Text-book of Chemical Physiology and Pathology," Longmans, Green, and Co. The most complete treatise which, however, is only suitable for advanced students, is Gamgee's "Physiological Chemistry," published by Macmillan and Co.—ED. L.

"AN APPEAL TO BROTHER PRACTITIONERS."

To the Editors of THE LANCET.

SIRS,—Did it ever strike your correspondent, "M.D.," that his pain in his hip-joint might be a neurosis—neuralgia—which, in my experience, is much more developed by climatic changes than "rheumatism," the latter also usually being improved by exercise? All "gout" is atonic nowadays, often showing itself as neuralgia pure and simple, and one constantly finds people calling a pain, especially if near a joint, "rheumatism," and considering the treatment for neuralgia and rheumatism is essentially opposite the mistake is a fatal one as regards curing the pain. I believe "M.D." would not find it to be a dangerous experiment were he to try a tumbler of Guinness's stout at luncheon and dinner—say, for a week—then alternate with the same quantity of champagne. Frequent gentle exercise with light dumb-bells (three pounds each) and a Turkish bath twice a week before dinner might in addition prove useful.

I am, Sirs, yours faithfully,

July 9th, 1900. F. ORTON, M.D. Dub.

"THE TREATMENT OF MORPHINOMANIA."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent's inquiry in THE LANCET of July 7th I had recently occasion to write to Dr. Emmerich of Baden-Baden *re* his treatment for morphinomania. Dr. Emmerich informed me that the articles he employs are already known pharmacopœial preparations, that he does not provide his material for general use, but retains it solely for his "Heilanstalt" (health resort). I enclose a pamphlet issued by Dr. Emmerich but regret that I cannot supply your correspondent with papers written by Dr. E. I had two which treated on "Morphinismus." From one I abstracted the following note: "The substitute (for morphia) is stated to be a plant decoction without a trace of narcotic, to which a considerable quantity of bodies containing tannin has been added, producing a mixture of acrid taste. This mixture precipitates morphia completely from its solutions."

I am, Sirs, yours faithfully,

W. HARRISON MARTINDALE.

New Cavendish-street, W., July 9th, 1900.

"A GOOD BICYCLE SADDLE."

SEVERAL correspondents have written in reply to our correspondent "B" in THE LANCET of July 7th, with regard to a bicycle saddle that does not chafe the thighs. Two strongly recommend the "Esmond" saddle, which is so suspended that it has a forward and lateral motion, the saddle moving with the rider. "There is no chafing and perineal pressure is almost abolished," says one of the writers. Another correspondent recommends the "Christie" saddle. Brook's B 90 receives two testimonials, while Dr. Churchward's patent hygienic saddle is said by the inventor not to produce "perineal pressure or friction" and receives the encomiums of an independent rider. Dr. Churchward, whose address is 206, Selhurst-road, South Norwood, writes to say that he will be willing to let any member of the profession have one of his saddles for approval if they will apply to him. One gentleman prefers a lady's saddle and finds the one that suits him best to be a Lycett pneumatic. From the correspondence we extract a hint that may prove useful to riders generally—namely, that by painting a saddle underneath twice a week with soft soap and paraffin the leather will become as soft as a glove.

A. A. B.—1. The *Ophthalmic Record*. 2. The Royal Eye Hospital, Southwark, or the Royal Westminster Ophthalmic Hospital, King William-street, Strand. 3. Swanzy's "Handbook of Diseases of the Eye" (Lewis, 12*s.* 6*d.*) for a general knowledge, or Professor Fuchs's "Text-book of Ophthalmology," translated by A. Duane (Lewis, 21*s.*), for more advanced studies.

Scandal.—So long as the tenants are orderly and well conducted—and our correspondent says that he has never seen anything to the contrary—we presume he can do nothing, but of course it depends upon the terms of the lease. Our correspondent is not the leaseholder. If he does not like the house he can leave it.

During the week marked copies of the following newspapers have been received: *Coventry Standard, Leeds Mercury, Bolton Journal, Sun (London), South Wales News, Southampton Observer, Nottingham Daily Guardian, Blackburn Weekly Standard, Liverpool Daily Post, Manchester Guardian, Bradford Observer, Birmingham Daily Post, Cornishman, Dundee Advertiser, Sussex Daily News, Oldbury Weekly News, Pioneer Mail, Times of India, Architect, Scotsman, Citizen, Builder, Yorkshire Post, Bristol Mercury, Newbury Weekly News, African Times, Devon Gazette, Umpire, British Invention, Kentish Mercury, Derby Mercury, Local Government Chronicle, Bristol Times and Mirror, Hertfordshire Mercury, City Press, Reading Mercury, Catholic Times, Surrey Advertiser, Local Government Journal, Brisbane Courier, Clifton Chronicle, The Telegraph (Brisbane), Nature, Justice, Chatham News, Blackpool Gazette, Leamington News, Dewsbury Reporter, Brighouse News Ashton Herald, Exmouth Chronicle, Goole Weekly Herald, Kettering Guardian, Nuneaton Observer, &c., &c.*

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Lonpon Throat (2 P.M. and 6 P.M.).

SATURDAY (21st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Dr. Davis: Nasal Obstruction. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. A. Baldwin: The Importance of Methodical Physical Examination.

TUESDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Consultation. (Medical.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.)—3.30 P.M. Dr. Batten: Subacute Combined Degeneration of the Spinal Cord.

WEDNESDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Mr. M. Robson: Clinical Lecture:—Chronic Pancreatitis.

THURSDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Bidwell: The Application of Plaster-of-Paris Splints.

FRIDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Consultation. (Ear.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mr. A. Anderson, York; A. J.; Messrs. Armour and Co., Lond.; Mr. E. Alcott Lond.; Automobile Club, Lond., Committee of; Association for Oral Instruction of Deaf and Dumb, Secretary of; Dr. D. W. Aitken, Lond.

Two Clinical Lectures
ON
MALARIA AND THE MALARIAL PARASITE.

Delivered at the Medical Graduates' College and Polyclinic,

BY PATRICK MANSON, M.D., LL.D. ABERD., F.R.C.P. LOND., C.M.G.,

LECTURER ON TROPICAL DISEASES AT ST. GEORGE'S HOSPITAL AND CHARING-CROSS HOSPITAL MEDICAL SCHOOLS AND AT THE LONDON SCHOOL OF TROPICAL MEDICINE.

LECTURE II.[1]

Delivered on Feb. 28th, 1900.

GENTLEMEN,—The morbid anatomy of malaria is fairly constant, consisting principally of enlargement of the spleen, congestion of the liver and portal circulation, and pigmentation of the spleen, liver, brain, and many other viscera. The microscopic anatomy, too, is fairly constant. In sections of all the organs mentioned, in the vessels in every instance, and, in the case of the spleen and bone-marrow, in the parenchyma also, there is to be found a remarkable deposit of the peculiar pigment which is so characteristic of malaria. This pigmentation arises from (*a*) the pigment belonging to and contained in living parasites—those little aggregations of pigment which I described as a feature in all mature malaria parasites—and (*b*) from the same pigment included in leucocytes, in endothelium, and, in the case of the spleen and bone-marrow, in the cells of the parenchyma. If you study sections of brain from cases of fatal malarial fever you will often see the capillaries distinctly outlined by the pigmented malaria organisms which they contain. The whole of the lumen of the capillary network is occupied by corpuscles containing little pigment masses. By carefully focussing you will see that each pigment mass is included in a red blood-corpuscle. Sometimes about the centre of a corpuscle you will see the mass of black pigment and surrounding this a body which you may be able to resolve into a cluster of minute sporules. This crowding of the vessels of the brain with parasites affords ample explanation of many of the phenomena of that type of malaria known as pernicious cerebral malaria. In sections of liver you will see a similar arrangement—pigmented parasites, and, much more abundantly than in the case of the brain, masses of pigment in leucocytes and here and there in endothelium. In the case of the spleen in one of the preparations which I show this afternoon you can see, besides the small parasites, each with its little mass of melanin in the capillaries, and besides small pigment-laden splenic cells, huge cells filled apparently with large block-like masses as of charcoal. The bone-marrow specimen exhibits similar appearances. Like the spleen, it contains the malarial pigment outside as well as inside the vessels. In the preparation of mesentery also you can trace a delicate capillary dotted here and there with pigmented sporulating parasites. In chronic malarial conditions you have secondary changes, fibrotic and so forth. These, of course, are not peculiar to malarial disease.

In addition to the black pigment, particularly in those cases of malaria which are accompanied with extensive rapid destruction of blood-corpuscles, you will find another type of pigment—a yellow pigment. This pigment is present in all conditions, accompanied by acute blood destruction. It is not peculiar to malaria; it is found in the hæmolysis attending extensive burns, in poisoning by chlorate of potash or arseniuretted hydrogen, in paroxysmal hæmoglobinuria, and so forth. This pigment is deposited hæmoglobin.

Another and important feature in the pathological anatomy of malaria, and one which you will discover by a careful examination of the blood in the living subject, is anæmia—an intense and, in acute cases, generally a rapidly advancing anæmia. If you examine a patient from time to time after successive malarial paroxysms you will find that the drop in the number of blood-corpuscles per cubic millimetre is very great indeed. In the course of a severe untreated attack the patient is reduced to a condition of intense pallor with a rapidity hardly equalled in any other disease. It is not so, of course, in every case, but in bad types you will find that this holds true. The cause of this excessive anæmia is not very obvious if we rely simply on examination of the blood from the finger for an explanation. If you place finger-blood from a case of malaria under the microscope you may find one or two parasites perhaps in each field. In many cases of severe malaria you will not find so many as that even; sometimes you will have to search through three, four, or five fields before you find one parasite.

How, you may ask, could so small a number of blood-destroying parasites account for anæmia so pronounced and so rapidly evolved? The reason is that the malaria parasite is not especially, or even ordinarily, a parasite of the peripheral circulation. It is a parasite of the blood of the central organs, as evidenced by the specimens shown this afternoon under the microscope. In a case of comatose pernicious malarial fever, with perhaps only three or four or five parasites in every field of finger-blood, you will find post mortem almost every blood-corpuscle in the capillaries of the brain carrying its own parasite. That is the reason why blood destruction is so prominent a feature in severe malarial attacks. The blood is not destroyed by the few straggling parasites seen in the peripheral circulation, but by the myriads of parasites in the blood of the viscera—the brain, the liver, the spleen, the bone-marrow, and so forth.

The behaviour of the leucocytes also is an interesting feature in the pathology of malaria. The polynuclear leucocytes decrease notably in number during the acute stages of malarial attacks; sometimes you may have a difficulty in finding them in the peripheral blood. The large mono-nuclear white cells increase as a rule and often contain malarial pigment. These large mononuclear corpuscles, as well as a certain number of the polynuclear corpuscles, carry the pigment to the spleen and there deposit their burden, which is taken up by the cells of this organ, producing the greater part of that enormous deposit of pigment so clearly illustrated by one of the sections under the microscope.

A peculiar feature clinically about malarial disease is its periodicity. This periodicity is accounted for by the periodicity and simultaneity of development of the parasites; they all seem to keep together as a swarm. At a particular time of the malarial clinical cycle you will find a certain form of parasite in the blood. Just before the explosion of the fever you will find a predominance of the rosette bodies; after the fever has subsided you will find the small form of the parasite as the predominant feature. and so on. Why should this be? Why should there be a conspiracy, as it were, among the different parasites all to mature at a certain time and all at the same stage? This simultaneity of maturation, so to speak, is the reason for the intermittence and regular periodicity of malarial fever. But what is the reason for the parasites observing this periodicity? The question is a very difficult one to answer. I believe the reason is twofold: first, the habit of the parasite to live a more or less definite number of hours; and, secondly, the diurnal rhythm in the periodicity of the physiological processes of the human body. At a certain time of the day in health the body temperature begins to rise and at a certain time it begins to fall; so with the tendency to sleep, to eat, to secrete, and to excrete particular substances there is a definite diurnal periodicity in the normal physiological cycle. This diurnal physiological periodicity, combined with the tendency of the parasite to live for a definite time impresses, I would suggest, the periodicity on the parasite of malaria which is so very characteristic of it and of the disease it produces.

So far as is known the lower animals are absolutely immune as regards the human forms of malarial disease. If you inject human malarial blood into a monkey there is no subsequent proliferation of the parasite and no fever. The same is the case with the dog or horse or other animals. Therefore in the lower animals there is complete immunity as regards the malarial parasite. We also know that certain human beings, very few it is true, enjoy a similar absolute immunity as regards this parasite. Some people coming into a malarial district contract the disease within a week or ten days of their arrival, others resist the disease for months, and a very few resist it permanently. That fact shows that *qua* the malarial parasite there is a varying degree of immunity in the same human body and in different individuals. I believe that this immunity possessed by the human body, like other physiological properties, has, as regards its amount a diurnal rhythm. At one time of the day the resistive power against a malaria parasite is greater

[1] Lecture I. was published in THE LANCET of May 19th, 1900, p. 1417.

than at another time of the day. I think that any malaria parasite which might enter or be set free in the blood when the immunising power of the body is at its height is likely to be destroyed by the resistive power. Should it happen that the power of resistance is at its minimum, then the parasite would survive, enter a blood-corpuscle, mature, and propagate its kind. In that way, it may be, the periodicity of malaria is caused—viz., by the combination of physiological conditions and the properties, so to speak, of the parasites.

We know when the new-comer arrives in a malarial country his first attack of malaria is usually a very severe one; it is usually either a continued or a remittent fever; that is to say, the fever does not exhibit in any marked way the definite periodicity which we are accustomed to associate with malaria. Apparently the parasites are permitted to enter the blood-corpuscles and mature at all times of the 24 hours. After a time, however, the body seems to become educated to a certain extent, so that by-and-by a definite periodicity is impressed upon the parasite and the continued fever after a time becomes remittent and by-and-by intermittent. I would interpret this by supposing that the body gradually acquires a certain degree of immunity and reaches at some time in the 24 hours the standard of absolute immunity and that in this way the parasite and the symptoms it gives rise to get a definite periodicity impressed upon them.

It is almost useless for me to attempt to describe the manifold clinical forms of malarial disease. We know that malarial fevers tend to assume a quotidian, a tertian, or a quartan type. We also know that in certain cases the quotidian becomes a remittent or continued fever. We also know that if we examine the blood in remittent or in continued malarial fevers we sometimes find in it the type of parasite characteristic of tertian, sometimes of quartan, sometimes of the æstivo-autumnal infection, and sometimes a mixture of two or even of all the types of parasites. At first it seems difficult to understand how a tertian or a quartan parasite could give rise to a quotidian fever. But such is the case and there can be no doubt that it can be explained. If you look at the blood of a patient with quotidian fever in very few instances will you find a quotidian parasite, which is amongst the rarest of malarial infections, if, indeed, it exists at all. You will find generally either a tertian, a quartan, or an æstivo-autumnal, which is also tertian in its periodicity. In the case of a quotidian fever arising from a tertian infection there are two generations of parasites, one which is half-matured and one which is practically matured. The half-matured parasites will produce the fever of to-morrow and of three days hence, the fully-matured will produce the fever of to-day and that of the day after to-morrow, and so on. A double quartan infection will produce a double quartan fever. You get fever to-day and to-morrow but no fever the day after to-morrow. A treble quartan infection, in the same way, will produce a quotidian fever. If the three forms of parasites concur you will have a corresponding mixture of clinical symptoms. You will easily understand how confused the resulting clinical manifestation will be from this fusion of forms, but with the microscope and the temperature chart you can unravel the clinical puzzle and read, so to speak, the writing in the blood.

Disregarding the ordinary intermittents, I will say a word about pernicious malarial fevers, a type which has been very much neglected by English writers and which is better understood by our French colleagues—at all events it is more dwelt on by them.

In the course of what appears to be an ordinary ague, and which we do not ordinarily associate with any particular danger, there is suddenly developed some alarming symptom which if it be not properly appreciated may prove fatal, and that in the course of a very few hours. These are called pernicious attacks (*accès pernicieux*), and are classified under two headings, one conveniently called "cerebral" and the other "algid," the latter being associated with adynamic conditions, the former with manifest implications of the central nervous system.

The most common type of pernicious attack is known as "pernicious comatose malaria." The patient in the course of what apparently is an ordinary malarial attack suddenly becomes comatose; he cannot be roused, he has stertorous breathing, and unless skilfully treated he may die. Occasionally he comes out of this condition and temporarily recovers, but possibly at the next paroxysm of the fever he will fall into the same condition and die. Often these sudden attacks of insensibility are put down to apoplexy and very often a prognosis of hemiplegia is given. Fortunately for the patient this prognosis is sometimes upset by his coming out of the comatose condition without showing any evidence of hemiplegia.

Another type of pernicious cerebral fever, often mistaken for, and generally called, sunstroke, is hyperpyrexia. The patient has an attack of apparently ordinary ague, in the course of which, instead of his bursting out into perspiration and the symptoms subsiding when the thermometer reaches 105° F., the temperature may go on rising to 107° or 110° or even higher. Wild delirium merges into coma and death. Hyperpyrexial attacks are terrible things to witness. I have seen a good many and at first was prone to fall into the ordinary mistake of diagnosing heat-stroke. They occur very often during oppressive weather and are common in intemperate people. The diagnosis of heat-stroke, under the circumstances, is a somewhat natural one to make. On more careful consideration, particularly if the patient's blood is examined or a post-mortem examination is made, you will find, either from the presence of parasites or from pigmentation in the viscera, that the patient died not from heat-stroke but from malarial poisoning. Thus malarial coma and malarial hyperpyrexia are the most frequent and important of the cerebral pernicious types. But there are other forms: a not unusual one, particularly in children, is the epileptiform seizure.

In tropical countries it often happens that the first intimation of malarial infection in a child is an epileptiform seizure. Perhaps two days later there is a similar attack. You are inclined to give a gloomy prognosis; you tell the mother that the child is possibly an epileptic and you prescribe bromide. If you wait for 48 hours longer there is a third seizure and then if you use the microscope and the thermometer you will find that the child is not suffering from true epilepsy but from malarial fever. In adults also you sometimes have strange periodic seizures. One is a suddenly developed aphasia. I have seen this on more than one occasion. You are asked to visit a patient and you find him in bed exhibiting all the peculiarity of some form of aphasia, unable to speak, or using wrong words, misplacing them, and so on, and you are prone to diagnose grave cerebral disease. Occasionally the extrinsic muscles of the eyes are affected with some form of paresis. These cases are more common than is supposed but they are very frequently overlooked.

An explanation of these and similar conditions — the comatose cerebral attacks, the hyperpyrexial attacks, the epileptic seizures, the paretic conditions—is supplied by the brain sections shown under the microscope. You will see that the capillaries of the brain are crowded with malarial parasites. Should one particular centre of the brain be specially affected by the parasites, as, for instance, Broca's convolution, then you have a corresponding symptom. Should the heat-regulating centre—if there be such a centre—be selected then you may have hyperpyretic conditions. The algid attacks are somewhat rarer but they are equally important. It is necessary that one should be aware that such attacks do occur. A malarial fever very like cholera is not an unusual thing in certain districts. The patient, instead of getting an ordinary malarial attack, is suddenly seized with choleraic symptoms—vomiting, purging, rice-water stools, cramps, vox cholerica, and all the other signs of epidemic cholera. If you inquire into the history you may learn that he had malarial attacks perhaps only one or two days before. You examine the blood and you find malarial parasites, and if you treat the patient for malaria you will cure his cholera. It is well to recollect the possibility of such attacks in tropical countries. Dangerous syncopal attacks may occur in association with the symptom which we usually hail as heralding relief in a malarial paroxysm. Profuse perspiration occurs till the bedding is drenched; if the patient gets up and tries to stand he has, it may be, a fatal syncopal attack. Sometimes profuse sweating occurs at the very commencement of the fever paroxysm; the patient is cold and algid and the profuse sweatings may end perhaps in collapse. In other forms vomiting, dysenteric conditions, and so on occur. Indeed, the variety of clinical features exhibited in malarial infections is too great for me to fully discuss on this occasion.

A practitioner in tropical countries ought always to suspect that any sudden and inexplicable attack may be attributable to malaria. I would emphasise the word *may* because I do not wish it to be understood that such an attack *must* be malarial. We should not conclude, as is so often done, that every case of disease connected with the tropics which we

cannot diagnose is malaria; still, we ought to suspect it. There is one important type of what is believed to be malarial disease which has of late come into prominent notice, partly in consequence of the opening up of Africa and partly in consequence of the utterances of a well-known pioneer in pathology—Professor Koch. I refer to blackwater fever. This is a disease which, strange to say, has not been recognised till within the last 30 or 40 years. If you search the writings of the old Indian physicians you will find no mention of blackwater fever or of any corresponding disease. Some time in the "fifties" certain French physicians first drew attention to its occurrence in one island off the coast of Madagascar, and since that time the disease has been recognised in the West Indies, in South America, in the southern parts of the United States, and in the Malay Archipelago. It is known to be the most common cause of mortality among Europeans on the West Coast of Africa. It exhibits all degrees of intensity. A patient resident in one of the endemic districts who perhaps has had many attacks of ordinary malarial fever develops what at first he considers as one of his usual malarial attacks and he does not think much of it. Suddenly he is seized with severe rigor. (Strange to say, rigor, so prominent a symptom of agues and intermittent fevers in the temperate zones, is singularly rare in the tropical zones. In those countries in which malarial fever is a really dangerous item in the pathology rigor is not as a rule a prominent malarial symptom. In blackwater fever it is different in this respect—violent shivering is a usual initial symptom.) The patient may then be seized with the desire to pass urine; he is astonished to find that his urine is black. He goes on urinating frequently and the urine continues to have this peculiar colour. He looks at himself in the mirror and finds that his face has become as yellow as saffron. This condition is associated very generally with fever, vomiting of biliary material, pain about the loins and back, and severe hepatalgia and intense prostration. Often as the case advances the patient exhibits all the symptoms of sudden profuse hæmorrhage (doubtless associated with the great discharge of hæmoglobin), giddiness, sweating, sighing, restlessness, and syncope. In many cases fortunately the hæmoglobinuria—for such is the symptom—gradually disappears with the fever, the urine becoming less dark and after a time natural in colour, but the patient is left intensely anæmic and jaundiced and only slowly recovers. Very likely there is no relapse. In some cases, however, the symptoms do not subside, the hæmoglobinuria persists, and the patient may die from syncope or exhaustion; or, the hæmoglobinuria persisting, the urine gradually gets smaller in quantity and becomes thicker and almost glutinous, being reduced to two or three ounces in the 24 hours. It may be entirely suppressed and the patient may die with uræmic symptoms, or he may recover temporarily and the discharge of urine may be re established, but in two or three days or weeks he may die with symptoms of acute nephritis. Blackwater fever is a terrible disease; the mortality from it is enormous, amounting in some epidemics to as much as 50 per cent., in others to 25 per cent. Occasionally the mortality is as low as 10 or 15 per cent. The disease, however, is always a dangerous one, and it is one that is almost sure sooner or later, if the patient remains in the endemic area, to recur. The liability to recurrence unfortunately does not cease when the patient has left the endemic area, for, as with other malarial disease (if it be a malarial disease), symptoms are liable to return or even to appear for the first time after the patient has returned to Europe. I have seen a good many cases in England. Only three weeks ago I saw a young Englishman die from this disease in London. I do not know how long the liability to recurrence persists after return to temperate climates, but certainly it persists for five months. I have known of such cases.

There are certain popular fallacies about the diagnosis of malaria which it is well to bear in mind. The principal of these is that everybody who has passed through the Suez Canal, or who has visited Rome, or has lived in a tropical country, is the subject of malarial infection. That is about the commonest and the most vicious fallacy among practitioners in this country. Fortunately many tropical lands are absolutely free, or relatively free, from malaria; it is only in certain places even in tropical countries that malaria exists. Do not, therefore, when a patient comes from a tropical country complaining of some more or less obscure symptoms, jump to the conclusion that those symptoms are the outcome of a malarial infection. One sees curious mistakes in connexion with this popular fallacy. I recollect reading some time ago in one of the medical papers two cases of what was called "malarial neuritis." I was very much struck with the evidence for founding his diagnosis of malarial neuritis with which the writer appeared to be satisfied. One patient was a sailor, and doubtless in the course of his life as a sailor he had visited malarial countries—*ergo*, his neuritis was malarial; that was all the evidence for the diagnosis. The other case was very much the same, the patient being a sailor who at one time—many years ago—had had malaria; and that was all the evidence which the writer had for diagnosing the case as one of malarial neuritis. This is typical of the diagnosis one often finds of obscure disease in patients from tropical countries.

Few diseases are so easily diagnosed as malaria. We have three pathognomonic tests which, intelligently applied, are absolutely infallible. There is the clinical test of periodicity, but diurnal periodicity is of no value in the diagnosis of malaria. A periodicity of 24 hours is shared with malaria by many diseases, but it is otherwise with a periodicity of 48 hours or 72 hours. Only one pathological condition exhibits this feature and that is the malarial infection. Any disease exhibiting a tertian or quartan periodicity is certainly malarial. But I strongly dissuade you from putting any reliance upon quotidian periodicity in the diagnosis of malaria; it is most misleading and constantly gives rise to mistake. If a patient has well-marked rigor followed by pyrexia, and that by profuse perspiration, and if this occurs day after day, do not jump to the conclusion that the case must be malarial because of the periodicity and because the patient is from a tropical country. In diagnosis quotidian periodicity should be absolutely ignored. I have seen a patient with well-marked abscess of the liver, the patient himself being a medical man, and yet because he had rigor, pyrexia, and perspiration day after day he was sure that he was suffering from malarial fever, and he was taking quinine in consequence. Nearly all suppurative processes are attended by a fever with a quotidian periodicity more or less marked. Osler says that he never sees a case of abscess of liver that has not been drenched with quinine, the diagnosis of malaria having been made doubtless in consequence of the quotidian recurrent pyrexia. Many diseases—ulcerative endocarditis, surgical kidney, gallstones, syphilis, tubercle, almost every disease with febrile associations—may exhibit quotidian periodicity. But it is otherwise with tertian and quartan periodicity; these are both absolutely pathognomonic of malaria. Then we have the therapeutic test—the test by quinine. Quinine properly administered in a case of malarial disease in 48 hours is in my experience invariably followed by abatement of the symptoms. If you give a patient quinine for 72 hours and there is no abatement of fever you should revise your diagnosis; the patient is not suffering from malaria. There is no use in persisting with quinine for days and weeks on the supposition that the case is malaria. You can poison the malaria parasite with quinine as certainly as you can poison a man with arsenic.

It is not sufficient, however, to rely on the therapeutic test, because in many instances we have no time to wait for its application, as in grave cerebral attacks. In such cases you cannot wait to see the effect of quinine before making the diagnosis. By the time the diagnosis is established the patient might be dead. It is necessary to have some more rapid means of arriving at the conclusion of what is the matter with the patient. That is supplied by the microscope; it is an immediate and invaluable test for malaria. Practitioners in tropical countries fail in their duty to their patients if they do not acquaint themselves with the application of the microscope in the diagnosis of malaria. For the practitioner nowadays to undertake the care of life in tropical countries and to be ignorant of the use of the microscope in malarial diagnosis is positively culpable. I think that the practitioner who visits a tropical country and pretends to take care of patients there and who cannot use his microscope is like a physician in England who is ignorant of the use of the stethoscope. Of the two instruments by far the more valuable in tropical practice is the microscope. The microscopic test is easily applied. All that is required is a high-power lens, a $\frac{1}{12}$ objective, a fair illumination and two or three slides, some cover slips, and a patient. In five minutes you can tell whether the patient is suffering from malaria or not. Anyone who ignores

this simple method is not only foolish but I say he is also sinful.

One word in conclusion about the treatment of malaria. This resolves itself into one word, the use of quinine. We have in quinine really a specific (about the only real specific in the Pharmacopœia), and if we can properly apply the specific in 99 cases out of 100 we can save the patient from the effects of the parasite. It is one thing, however, to possess the specific and it is another to be able to apply it. In cases of violent remittent fever and grave cerebral attacks the patient may be vomiting and unable to absorb the drug, or he may be insensible and unable to swallow it. You must have recourse to other means and give five or ten grains of a soluble salt of quinine hypodermically or rather intra-muscularly. This may save the patient; he may die without it. At one time this method of using quinine got out of favour because in several instances the hypodermic injection had been followed by tetanus and the death of the patient. Now, tetanus is not caused by quinine; it is caused by the tetanus bacillus. Death from tetanus following on the hypodermic injection of quinine is caused by the culpable carelessness of the physician who, in ignorance of course, has used an injection containing the tetanus bacillus. The hypodermic injection of quinine, though painful and often objected to by the patient, is free from risk provided that ordinary precautions are taken to render the syringe, the skin, and the solution aseptic.

A certain number of patients appear to have peculiar sensibilities as regards the action of quinine. In some it gives rise to urticaria, in some to peculiar toxic effects, and therefore to some patients it cannot be given at all. In these cases methylene blue is of service. I have not much experience of its use; I have not the same faith in it as I have in quinine. Professor Koch is one authority for its use. It is given in doses of from three to five grains three or four times a day. Another and graver accusation against quinine is that it is apt to give rise to hæmoglobinuria. Professor Koch's utterances in regard to this have been somewhat misunderstood. Many people suppose that Koch said that quinine gave rise to—is the cause or virus, as it were, of—hæmoglobinuria. What he did say was that quinine under certain conditions brought on hæmoglobinuric symptoms, and what he said is in my opinion, true, only he has expressed himself somewhat vaguely. A man is responsible not for his words only but also for the effect which they produce, and Koch's words have had a most prejudicial effect in this matter. In consequence of what he has said quinine is looked upon with suspicion, if it be not absolutely tabooed, in some tropical countries. This is unfortunate, for even if quinine is a danger in certain cases, if it does tend to produce hæmoglobinuria in some cases, it is not a one-hundredth part so dangerous in this respect as the malaria parasite. Of the two evils the parasite is infinitely the greater one, and therefore the withholding of quinine from a patient in whom the parasite is circulating is more apt to be followed by blackwater symptoms than if the drug be given.

In cases of blackwater fever examine the blood and if you find in it the fever forms of the malarial parasite give quinine; if you do not find the parasite withhold the quinine. This is a good rule. It is a fortunate circumstance that hæmoglobinuria frequently kills the parasite in the circulation. If you look at preparations of blood made just before the appearance of hæmoglobinuric symptoms you will often find the malarial parasite; if you examine the blood of the same patient just after the appearance of the hæmoglobinuric symptoms you may find a very few parasites; and if you examine it a little later, say 12 hours after, you may fail to find any parasites at all. Apparently there is a process of natural cure caused by the parasite itself when it brings about hæmoglobinuria. That should encourage us to withhold quinine in many cases of blackwater fever, especially when the parasite cannot be detected by patient and competent observation with the microscope.

INSPECTION OF COWS TO DETECT TUBERCULOSIS.—The Dartford Urban Council, after communication with the urban district councils of Bexley, Erith, and Dartford Rural Council have jointly appointed for one year Mr. A. Edgar, F.R.C.V.S., on terms agreed upon, to undertake the duties of periodically inspecting cows in the respective districts under their control.

A Clinical Lecture

ON

MODERN METHODS OF AMPUTATING AT THE HIP-JOINT,

WITH A TABLE OF 15 CASES.

Delivered at the General Hospital, Birmingham, on March 1st, 1900,

BY THOMAS F. CHAVASSE, M.D., M.C. EDIN., F.R.C.S. EDIN. & ENG.,

SENIOR SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

GENTLEMEN,—The patient here presented is rather an unusual case, for you will see that she has had both her lower limbs removed at the hip-joint. The clinical history is briefly this. Her age at present is 27 years and for some years she had suffered from tuberculous caries of the tarsal bones of the right foot, so that in October, 1895, it was necessary to perform a Symes's amputation at the ankle-joint. Some months later tuberculous osteitis manifested itself at the end of the tibia, and in October, 1896, Stephen Smith's amputation was performed at the knee joint. The stump never properly healed, and, becoming the site of another tuberculous deposit, she was re-admitted into hospital in May, 1897, and on the 29th of that month I removed the femur at the hip joint. Healing was extremely protracted, and it was six months before the stump was sound. She was then lost sight of for some time, but she re-appeared at the hospital in April, 1899. The left foot and ankle were found to be much swollen and œdematous and there were signs of fluctuation on the outer side of the ankle-joint. On the lower third of the leg was a large tuberculous ulcer which had existed for three months; the knee-joint was filled with fluid and presented the usual symptoms of tuberculous disease. In the middle of the quadriceps extensor was a large caseating mass of the size of a clenched fist. The patient was emaciated and hectic. After a consultation with my colleague, Mr. Haslam, it was deemed desirable on April 20th to remove the left limb at the hip-joint. The healing of the stump was again protracted, but, as you now see, only two minute spots at the top of the external incision remain unhealed. The general health of the patient seems good, she has gained flesh and she takes her food and digests it well. At present there are no signs of any tuberculous deposit in any of the other joints of the body or in the internal organs.

I have now performed 15 amputations at the hip-joint upon 14 different individuals and herewith is presented in tabular form the sex and age of each patient, the disease for which the operation was undertaken, the plans adopted for restraining the hæmorrhage, the method of operating, and the results. On looking at the table you will see that in the series only two methods of operating have been practised. In the first anterior and posterior skin-flaps have been shaped from without inwards, and the muscles and vessels divided high up as close as possible to the pelvic bones by a circular incision. This method has been adopted in three cases (Cases 1, 2, and 9), each time with success, and theoretically it is the best method to be adopted when a malignant neoplasm has to be dealt with. Its drawbacks are that it undoubtedly increases somewhat the shock attendant upon the operation and the high division of the muscles necessitates the direct compression of the aorta for the restraint of hæmorrhage.

The second method is for practical purposes that known as the external racket operation and is really a combination of the vertical and circular incisions. The names of many eminent surgeons are associated with this plan of operation, notably, Furneaux Jordan, Lister, Esmarch, &c.; but I have preferred to speak of it as the external racket method as thereby the general principle of the operation is more likely to be impressed upon your minds than if it be associated with the name of any distinguished surgeon of the present or past generation. The precise steps will differ somewhat in a case in which the operation is undertaken for malignant disease from those taken when it is performed for the disease

of the hip joint. In the latter condition the lower the mass of muscles of the thigh are divided the less the shock to the patient, and the bone can be readily shelled out, subperiosteally or otherwise, especially when excision of the head has previously been performed, without interfering materially with the muscles on the inside of the thigh. For drawing special attention to these facts and demonstrating their utility in actual practice Mr. Furneaux Jordan, of this city, deserves all praise. In case of a malignant growth it is obvious that the further all the soft structures are divided from the growth the better are the prospects of success as far as recurrence in the stump is concerned. In such instances a circular incision may be made round the limb at about six inches from Poupart's ligament, merely dividing the skin and subcutaneous tissues; a vertical incision is then made commencing just above the great trochanter and carried downwards on the outer aspect of the limb until it meets the circular cut previously made. The skin is then reflected upwards all round as high as the lesser trochanter. At this point all the muscles and other soft parts are cut through by a circular incision reaching the bone, the femoral vessels are at once seized and ligatured, and steps are taken for the disarticulation of the head of the femur. For this purpose it is better to change the amputating knife for a large scalpel, as with this the joint is more readily entered, the ligamentum teres divided, and the head of the bone dislocated. A few cuts with the knife behind the head of the femur enable the removal of the limb to be completed. The remaining known vessels are then secured and the wound is closed in the usual manner as expeditiously as possible, after the tourniquet has been removed and any spouting arteries ligatured. It is better to drain the acetabulum either with a fair-sized drainage tube or with an iodoform gauze drain.

There is another method to which I should like to direct your attention and which might be especially serviceable when the operation is undertaken for an emergency and skilled assistance is not attainable. Personally I have had no experience of the operation, but it is described by Dr. W. L. Estes[1] as the "gradual dissection method" and is practically a modification of the German operation suggested by Professor Rose. The first step of the operation is the ligation of the common femoral vessels at Poupart's ligament and division of the same between double ligatures; short anterior and posterior skin flaps are then formed from without inwards, and the soft parts are divided by gradual dissection close up to the pelvis, all known vessels being secured before they are divided, the smaller ones being clipped immediately afterwards. It is at once apparent that the method takes more time for its accomplishment than the other plans, but it can be carried out with one assistant, who need not be a very highly trained one, and the surgical apparatus required is simple and slight.

The two main risks of the operation for amputating at the hip-joint to which I propose shortly to direct your attention are hæmorrhage and shock.

Hæmorrhage.—Many ingenious inventions have been introduced to obviate hæmorrhage, such as tourniquets, a rectal staff, clamps, &c.; but until a few years ago most practical surgeons relied mainly upon rapid execution and the dexterity of an assistant in digitally compressing the vessels before and after division. I may at once say that owing to a plan advocated by Professor Wyeth of New York City any fears as regards profuse hæmorrhage during this operation exist no longer. Professor Wyeth's idea is directed to the prevention of the slipping of the elastic tourniquet which is applied over the femoral vessels at the moment when the disarticulation of the limb is effected. This is accomplished by means of two steel skewers or pins, which have a head, and are rounded and sharp pointed at the other end, ten inches in length and three-sixteenths of an inch in diameter. They may seem rather formidable instruments at first sight, but for an adult in actual practice they are none too strongly made, as the strain upon them to keep the elastic tourniquet *in situ* during the necessary manipulations is severe. I show you two pins that I have used in three operations upon adults and you will perceive that they are considerably bent, this being accomplished by the tourniquet pressure. The elastic tourniquet employed should be half an inch in diameter and long enough to encircle the top of the thigh four or five times. In young children, however, a tourniquet of very much smaller calibre will suffice and instead of Wyeth's pins I employ two much smaller steel skewers such as a cook uses for trussing game or chickens for cooking purposes and which can be procured at any ironmongers, and I find that they answer very well. They are not, however, trustworthy for an adult, and on one occasion, when using them on a full-grown person, the outer one snapped off short and becoming useless had to be replaced in the middle of the operation. Fortunately the main vessels had been secured before the mishap occurred. The accompanying illustration will show the use of the pins. It is taken from Professor Wyeth's paper.[2] The outer needle is introduced a quarter of an inch below the anterior superior iliac spine and somewhat to its inner side, passing through the muscles to the outer side of the hip, and is made to emerge three or four inches from its point of entrance. Its direction should be a little backwards so as to keep it as far as possible from the great trochanter of the femur. The inner needle is inserted through the skin and the adductor longus muscle half an inch below the fork in the male and is brought out one inch in front of the tuberosity of the ischium. To protect the operator's hands a piece of cork is applied to the sharpened end of each needle as soon as it is in position. The limb is then emptied of its blood by elevation and the elastic tourniquet is wound tightly round the limb above the pins. Wyeth recommends that a compress four inches square and two inches thick be laid over the femoral vessels as they cross the brim of the pelvis before the tourniquet is applied. I have not, however, carried out this detail in any of my own cases. By applying the tourniquet effectively in the above manner hæmorrhage both from the anterior and posterior vessels is absolutely prevented, but the limb becomes very tense, and I have found that it takes a little more time to complete the disarticulation, as the free movements of the operator are somewhat hampered by the presence of the tourniquet and the pins, but this is quite a small matter as compared with the advantages obtained by immunity from bleeding. Before the pins and tourniquet are removed practically all the known arteries can be secured, and although there may be some general oozing subsequently it can be readily restrained by a good-sized flat sponge. On looking at the table you will see that eight cases out of the 15 have been treated in this manner and with, I think, such marked success that I have no hesitation in saying that at the present time it is the best method which we have at our disposal.

The second plan I have employed to restrain hæmorrhage is by directly compressing the abdominal aorta by placing a fair-sized pincushion or pad over it and protecting the spine and flanks of the patient with pads of lint, then encircling the abdomen with a thick elastic tourniquet. It is a very effective method, especially in children, but it is not so desirable in adults because the cushion is more apt to slip and the tight constriction necessary to stop the arterial circulation compresses also the intestines and may also embarrass the breathing of the patients. It has the advantage of not interfering in any way with the part to be operated on and permits the unimpeded formation of anterior and posterior skin flaps and the high division of the muscles attached to the pelvis, whilst the manipulations of the hip joint can be freely effected. It has been employed four times in the series (in Cases 1, 2, 4, and 9), and invariably with success as far as loss of blood is concerned.

The third method employed in the series is digital compression by a skilled assistant, and although in the three cases (Cases 3, 5, and 6) this has been carried out and the femoral vessels have been secured at an early stage of the operation, and I have also had the great advantage of the skilled fingers of my colleagues, yet I am bound to say that all three patients lost more blood during the operation than those subjected to the other two methods and that most of the blood so lost came from the vessels posterior to the joint.

Shock.—The shock will generally be severe, but its dangers can, I think, be reduced by certain routine observances. In the first place, the theatre or room in which the operation is conducted should be well warmed; 65°F. is a good temperature. Then a hot water table or a water bed filled with hot water for the patient to lie upon should be provided,

[1] Lehigh Valley Medical Magazine, January, 1894, and Philadelphia Polyclinic, March 24th, 1894.

[2] Annals of Surgery, vol. xxv., 1897.

and the extremities, excepting that to be removed, and the trunk should be enveloped in cotton-wool. The apparatus should be at hand for the intravenous injection of normal saline fluid and it is as well if the basilic vein of the arm on the opposite side to which the removal of the lower extremity is to be effected is dissected out by an assistant before the operator actually commences. I say on the opposite side because it is advisable to undertake the injection when the closure and dressing of the wound are being performed and the manipulations of the injector will thus not be impeded by the chief operator and his other assistant. I have now carried out the injection of saline fluid in my last eight cases and the effects have been so marked, and I believe so beneficial, that in my judgment it ought to form part of the routine of the operation in every case. One cannot say that it will invariably save life, still, it may be the means of tiding the patient over the most critical time and so allow the opportunity for the administration of liquid foods and the exhibition of other remedies.

The most prominent symptoms of the shock following the operation are cold clammy sweating of the body, cold extremities, extreme restlessness, small rapid pulse, and constant efforts at vomiting.

All the cases in the series, excepting Case 6, have been hospital cases, and in this class of patient it is often extremely difficult to make the patients or their friends realise the necessity for the removal of the limb. Cases 3, 10, and 13 are examples. Case 3 was that of a man, aged 32 years, who had had excision of the left femur performed and a large portion of his acetabulum removed for long-standing hip-disease. Osteitis of the shaft of the bone ensued and the amount of pus discharged daily was more than a pint, yet for more than nine months after he had been informed that it was impossible to save the limb he refused to have amputation performed. The patient in Case 10, a girl aged 14 years, had her hip-joint explored in June, 1896, and it was found that the acetabulum was perforated and the tuber ischii carious, yet her parents declined to have the major operation carried out until January, 1897. She recovered well from the shock of the operation but she gradually sank and died on the evening of the third day exhausted. In Case 13, that of a girl aged eight years, the head of the left femur was excised on Feb. 26th, 1897. By the beginning of 1898 the cicatrix broke down and disease of the acetabulum and shaft of the femur were detected, but the parents refused to have amputation performed for 14 months, by which time there was amyloid disease of the liver, the edge of the organ being readily detected below the ribs, and the urine contained albumin and waxy casts, besides being increased in quantity. When she was admitted into hospital in April, 1899, there were no fewer than 12 discharging sinuses round the hip-joint, the pus being of the most offensive description, yet after the operation the health of the child immediately began to improve, the size of her liver gradually diminished, the polyuria and albuminuria disappeared, and she is to-day alive and well, although in September last it was necessary to remove a loose piece of the pelvis and to scrape out several unhealed sinuses.[3]

Age is an important factor to be considered when a successful issue is sought for, and at one time I thought that in those patients much over 20 years of age who had to undergo this operation each added year of life increased the risk in a disproportionate degree. But the certain restraint of hæmorrhage and the injection of normal saline fluid before the patient is removed from the table has modified this idea. Eight of the patients in the tabulated cases were well over this age and of these six recovered. The oldest patient was 56 years of age, and he had been an inmate of the hospital in November, 1898, but then declined to undergo amputation. Nearly three months afterwards, when the sarcoma had increased very much in size, he was going upstairs at his own house and slipping on a step he felt his femur break in the situation of the neoplasm. This induced him to return to the hospital to have the limb removed and although convalescence was slow the stump was soundly healed in two months. Perhaps, therefore, we are justified in concluding that modern methods of performing the operation have considerably reduced the age mortality.

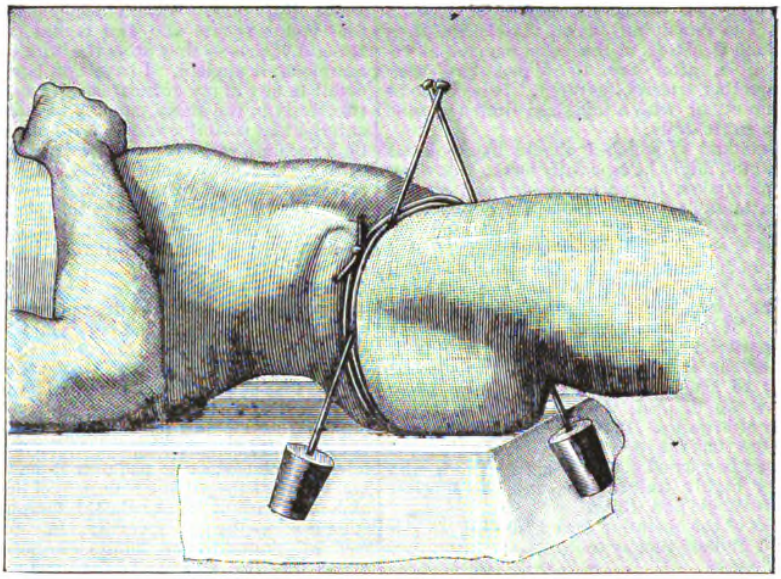

Illustration showing tourniquet and pins in position.

Pregnancy need not be considered to be a bar to the operation. In Case 8 the woman was 29 years of age and was six months pregnant, yet she bore the operation well and did not miscarry until a month afterwards, when the stump was practically healed. She survived the operation long enough to give birth to a healthy child after leaving the hospital. Case 15 was a woman, aged 23 years, whom I saw in the Rugeley Cottage Hospital with Mr. H. D. Chapman. She was over eight months pregnant with her first child and had a fungating sarcoma originating in the head of the tibia and implicating the right knee-joint and the belly of the semimembranosus muscle. We decided in consultation to induce premature labour and ten days later, a healthy living child having been born, the physical pain was so great that with the assistance of Mr. George Heaton and Mr. H. D. Chapman I thought it desirable to remove the entire

[3] The patient now (July, 1900) shows signs of caries of the second lumbar vertebra.

TABLE OF 15 CASES OF AMPUTATION AT THE HIP-JOINT.

No.	Sex and age.	Date of operation.	Disease.	Restraint of hæmorrhage.	Operation.	Result.	Remarks.
1	F., 15 years.	June 3rd, 1882.	Periosteal sarcoma of the lower third of the left femur.	Compression of the abdominal aorta by pin-cushion and elastic tourniquet.	Anterior and posterior skin-flaps and circular division of the remaining soft parts close to the pelvis.	Healed in six weeks. Recurrence in the right lung and death in six months.	Recorded in Brit. Med. Jour., vol. i., 1884.
2	M., 5 years.	Oct. 13th, 1882.	Morbus coxæ with necrosis and fracture of the lower third of the right femur.	Compression of the abdominal aorta by pin-cushion and elastic tourniquet.	Anterior and posterior skin-flaps.	Healed by Dec. 3rd, 1882.	The patient is still alive. Recorded in Brit. Med. Jour., vol. i., 1884.
3	M., 32 years.	Feb. 27th, 1883.	Left morbus coxæ of long standing. Head of the femur and part of the acetabulum removed in 1882.	Digital compression of the common femoral artery.	External racket method.	Death from shock on March 1st.	Large white kidneys were found post mortem. Brit. Med. Jour., vol. i., 1884.
4	M., 5 years.	July 1st, 1890.	Right morbus coxæ.	Compression of the abdominal aorta by pin-cushion and elastic tourniquet.	External racket method (sub-periosteal).	Sent to a convalescent home on August 22nd.	The patient is still alive; anterior excision was performed on April 26th, 1890. The acetabulum was diseased.
5	M., 16 years.	Oct. 17th, 1890.	Left morbus coxæ.	Digital compression of the common femoral artery.	External racket method.	Death from shock nine hours afterwards.	The patient was much emaciated from prolonged suppuration. At various times he had spent many months in hospitals.
6	M., 26 years.	May 31st, 1892.	Purulent osteo-myelitis of the right femur.	Digital compression of the common femoral artery.	External racket method.	Healed by June 8th.	The lower third of the thigh was amputated by Carden's method in November, 1891, for ununited fracture through the head of the tibia affecting the knee-joint. The patient fell on the stump a month before the last operation. There was a family history of tuberculosis.
7	F., 39 years.	Feb. 20th, 1896.	Endosteal sarcoma of the lower third of the left femur.	Pin method (Wyeth).	External racket method.	Death from shock in 10 hours.	The patient had sustained a fracture of the lower third of the femur six months previously.
8	F., 29 years.	March 26th, 1896.	Endosteal sarcoma of the lower third of the right femur.	Pin method (Wyeth).	External racket method. Intravenous injection of 15 ounces of saline fluid.	Healed by June 5th. Died on May 25th, 1897, from recurrence in the left lung.	The patient was six months pregnant at the time of the operation. Abortion took place on April 26th. The fœtus was dead.
9	M., 10 years.	Nov. 13th, 1896.	Periosteal sarcoma of the lower third of the right femur implicating the knee-joint.	Compression of the abdominal aorta by pin-cushion and elastic tourniquet.	Anterior-posterior skin-flaps and circular division of the soft parts close to the pelvis. Intravenous injection of half a pint of saline fluid.	The wound healed in three weeks except a small sinus.	The patient was alive 18 months after the operation.
10	F., 14 years.	Jan. 1st, 1897.	Right morbus coxæ. The acetabulum was perforated and the tuber ischii was carious.	Pin method (Wyeth).	External racket method. Sub-periosteal enucleation. Intravenous injection of half a pint of saline fluid.	Death from exhaustion on Jan. 4th.	The joint had been explored in June, 1896, but amputation was delayed at the request of the relatives of the patient.
11	F., 24 years.	May 29th, 1897.	Tuberculous osteitis of the stump following amputation at the right knee-joint.	Pin method (Wyeth).	External racket method. Intravenous injection of one pint of saline fluid.	Healed.	Syme's amputation at the ankle-joint for tarsal caries was performed on Oct. 8th, 1895, and Stephen Smith's amputation at the knee-joint on Oct. 9th, 1896, for osteitis of the tibia.
12	M., 56 years.	Jan. 26th, 1899.	Periosteal sarcoma of the lower third of the left femur.	Pin method (Wyeth).	External racket method. Rectus muscle infiltrated with new growth and divided high up close to the acetabulum. Intravenous injection of saline fluid (one pint).	Healed by March 27th.	The patient fractured his femur when walking upstairs on Jan. 23rd, 1899.
13	F, 8 years.	April 6th, 1899.	Left morbus coxæ. (Amyloid degeneration of the liver and kidneys.)	Pin method (Wyeth).	External racket method; intravenous injection of saline fluid (half a pint).	Sent to a convalescent home on June 6th. Sequestrum removed from the pelvis on Sept. 14th, 1899.	The head of the bone was excised on Feb. 26th, 1897, and scraping was done on Oct. 30th, 1897. The parents refused amputation in December, 1897.
14	F., 26 years.	April 20th, 1899.	Tuberculous disease of the left knee-joint and ankle-joint; caseating mass infiltrating the anterior muscles of the thigh. Tuberculous ulcer of the middle third of the leg.	Pin method (Wyeth).	External racket method; intravenous injection of saline fluid (one pint).	Healed.	This was the same patient as in Case 11.
15	F., 23 years.	Nov. 19th, 1899.	Endosteal sarcoma of the head of the right tibia, implicating the knee-joint and infiltrating the belly of the semi-membranosus muscle.	Pin method (Wyeth).	External racket method. Saline fluid injected into the cellular tissue of the axilla (12 ounces).	Healed.	The patient was over eight months pregnant with her first child and premature labour was induced 10 days before operation. Convalescence was retarded by a mammary abcess.

lower extremity. Convalescence, as might be expected, was tedious and was also complicated by a mammary abscess, yet with care and good nursing the patient has at length made a satisfactory recovery.

Of the 15 tabulated operations performed on 14 patients 11 of the patients recovered and four died, a mortality of 26·6 per cent. These cases were taken just as they occurred in practice and there was no selection of patients. In six instances the operation was performed for sarcomatous growths (four women and two men) and of these one died from shock. In the remaining nine the removal of the limb was undertaken for bone disease. The malignant cases were: Case 1, periosteal origin, round-celled growth; Case 7, endosteal, mixed celled with a preponderance of round cells; Case 8, endosteal, round-celled; Case 9, periosteal, mixed celled with a preponderance of round cells; Case 12, periosteal, mixed celled (round and spindle cells about equally distributed); and Case 15, periosteal, mixed celled with a preponderance of round cells. In three of the fatal cases the cause of death was shock pure and simple (Cases 3, 5, and 7), and it was after the death of the patient in Case 7 that I began systematically to inject saline fluid at the conclusion of the operation and since then no patient has succumbed from this cause. The patient in Case 10 rallied well from the immediate effects of the operation and did not cause anxiety until the third day when she began to sink slowly without any assignable cause except that apparently she had no rallying power. You will note that in this case as well as in Cases 3 and 5 permission to amputate was not obtained until a long time after the patient and the friends had been warned that the limb must be sacrificed. In fact, in three out of the four fatalities this prolonged wait was, I believe, the factor that caused the operation to be unsuccessful. Yet it is not to be wondered at that patients or their friends procrastinate in these instances, for a surgeon will generally find that assent to perform an operation is obtained readily enough when a really good prospect of recovery can be promised, whilst waiting is preferred if only a *dernier ressort* can be offered.

The tables of Dr. Sheppard of Philadelphia published in Ashhurst's "International Encyclopædia of Surgery"[4] show that 245 cases undertaken in civil practice give a mortality of 41·1 per cent. Mr. Frederick Page[5] gives 16 cases in which the operation was undertaken for disease in the Royal Infirmary, Newcastle-on-Tyne, with 10 recoveries and six deaths—mortality of 37·5 per cent. Dr. John Erdmann[6] of New York, collecting the figures of eight hospitals in that city, shows 18 cases with eight deaths, or a mortality of 44·4 per cent., but it is quite possible and probable that cases operated upon by a variety of surgeons will show a larger mortality-rate than if one particular surgeon had had the entire experience. Hence Dr. Estes[7] in his own tables had seven cases with one death, or a mortality of 14·2 per cent. But the most remarkable and most successful number of cases that have yet been collected are those of Professor Wyeth[8] who has brought together 69 cases in which hæmorrhage has been restrained by the application of his pin method. Four of these were primary cases and cannot fairly be included in the series as test cases. Their exclusion reduces the number to 65 in which the operation was performed for disease, with eight deaths, a mortality of 12 3 per cent. Of these eight one died from pneumonia on the thirty-second day when the patient was getting about, and one from tuberculous peritonitis on the eleventh day. If these be omitted as not being directly attributable to the operation we have 63 cases and six deaths, a mortality of 9·5 per cent., and one of these was due to a preventable cause, septicæmia.

From these figures I think that we are justified in concluding that an improved modern technique of operating, which includes the antiseptic and aseptic methods, has reduced the mortality of a formidable procedure to such really small dimensions that in suitable cases there is no longer any actual excuse for procrastination and that we are justified in urging operation in cases in which up to now we have been content merely to recommend it. If we can do this the immediate mortality of the operation will in future be possibly reduced even below Wyeth's figures.

ON RUPTURE OF THE APPARENTLY HEALTHY ŒSOPHAGUS.[1]

BY E. J. McWEENEY, M.A., M.D.R.U.I., M.R.C.P.I.,

PATHOLOGIST TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN; PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN; BACTERIOLOGIST TO THE LOCAL GOVERNMENT BOARD FOR IRELAND.

CASES of the above occurrence are rare—so rare that having lately observed one I have thought it well to collect the others which have been recorded and endeavour to present as accurate a picture as possible of this hitherto invariably fatal accident. The occurrence seems worthy of attention, not only on account of the interest attaching to its rarity and the peculiar and alarming symptoms with which it is attended, but also because the cases resemble each other so closely in previous history, signs, and symptoms that a correct diagnosis is quite within the bounds of possibility and modern advances in the surgery of the mediastinum seem to warrant a hope in the feasibility of successful intervention in some future case. I shall first detail particulars of a case under my own observation.

A man, aged 40 years (Case 17 in the table) was admitted to the Mater Misericordiæ Hospital at 1 P.M. on Nov. 18th, 1899, complaining of pain, not very intense, in the lower part of the chest and of swelling of the neck. His face was deeply cyanosed, he seemed to be gasping for breath, the pulse was quick and weak, and his general condition was somewhat collapsed. The neck and face were much swollen on both sides and palpation at once revealed the fact that the swelling was due to subcutaneous emphysema. His voice was low and hoarse and he spoke little and that with much difficulty. No treatment had any effect and the dyspnœa became more intense, the pulse weaker, and the emphysema meanwhile crept up to the eyelids and down the thorax. Death occurred at 8 P.M. His friends stated that he was of alcoholic habits and that he "had been more or less drunk every night for the last 20 years." He used to vomit every morning and was much given to "dry retching." On the evening before his death he had had tinned salmon for dinner and the following morning had retched worse than usual. Nevertheless he went to his work and whilst there noticed that his neck was swollen so that his collar became uncomfortably tight. His breathing became difficult and he felt a good deal of pain in the lower part of the chest. The exact period of onset of the symptoms could not, however, be certainly determined. At about noon he left his work and went home, whence his friends took him to the hospital.

Necropsy.—At the necropsy, which was performed by me 40 hours after death, the body was found to be that of a muscular middle-aged man. Post-mortem lividity was extensive and the features were almost obliterated from emphysema which extended from the eyelids to the mammary level. A brownish frothy fluid flowed from the mouth and nose. Post-mortem rigidity was well marked in the legs and elbow-joints, but was absent from the shoulders. On removing the sternum the cellular tissue of the anterior mediastinum was seen to be emphysematous. The left pleural cavity was partly obliterated by adhesions in front and behind it was filled with brown pultaceous fluid in which were bubbles of gas. The left lung was collapsed so far as the adherent pleura would allow and was almost solid with œdema. On removing the lung and sponging out the pleural cavity a slit-like aperture was seen at its lower and back part leading into the œsophagus. The right pleural cavity, almost obliterated by adhesions, contained a little brownish fluid, whilst the lung was covered behind with a layer of discoloured fibrinous exudate which felt greasy. It was intensely œdematous and almost airless. The pericardium contained four ounces of pink serum in which gas-bubbles appeared when the heart was raised up. These were seen detaching themselves from the point of entrance of the pulmonary vessels into the pericardium. The size and weight of the heart were normal, but it was very flabby; there were atheroma of the commencement of the aorta and some

[1] A paper read before the Pathological Section of the Royal Academy of Medicine in Ireland on May 4th, 1900.

fatty degeneration of the left ventricle was noticed. On removal of the heart and the lungs the whole contents of the mediastinum from the root of the neck to the diaphragm were seen coated with brown pultaceous material mingled with bubbles of gas. The matter was seen issuing from a slit-like aperture nearly 1·5 centimetres long in the anterior surface of the œsophagus immediately above the diaphragm. The opening was quite clean cut, with sharp edges from which a few small blood-clots projected—evidently thrombosed veins. The opening extended down quite to the level of the diaphragm and from its lower end a linear tear in the mucous membrane ran some distance into the cardia. There was no trace of ulceration and the wall of the gullet was fully as thick as normal. The wall of the gullet on each side of the rupture felt somewhat softened, but there was no discolouration of the mucous membrane. The mucosa of the stomach was, however, distinctly discoloured—blackened—with hæmorrhagic erosions at the cardiac end, and was streaked with dark lines corresponding to the veins. It was decidedly softer than normal, but could not be said to have been digested. It contained a good deal of brownish fluid identical with that found in the pleural cavities and mediastinum. The abdominal organs seemed healthy, except the liver, which was enlarged and fatty, but, contrary to expectation, not in the least cirrhotic. The omentum was much infiltrated with fat and the pelvis contained a few ounces of serum.

Morbid histology.—The specimen was dissected out and placed in 20 per cent. solution of formalin. The removal from the side of the rent of pieces of tissue comprising the entire thickness of the gullet wall could of course not be practised without materially injuring the macroscopic appearance of the specimen. This drawback was, however, the more readily put up with, because, so far as could be ascertained, no detailed microscopic examination of such a case had ever been published. Three pieces of tissue were therefore removed from different levels at one side of the laceration, comprising the edge of the actual rent and imbedded in paraffin, whilst a much larger piece, comprising a nearly complete transverse slice of the œsophagus, was taken from a point below the lower end of the rupture, so as to include the above-mentioned tear in the mucous membrane, and imbedded in celloidin. This gave the best results as the formalin fixation proved a little too "light" for the best class of paraffin work. 1. The *epithelium* at the level of the rupture was well preserved except on the top of the folds that projected into the lumen. In the crypt-like spaces between the folds it was particularly well preserved and the prickle-junctions of the cells were quite distinct; about 0·1 millimetre from the edge of the rupture it ceased quite suddenly. The tear above mentioned as prolonging the rupture proper down into the stomach was found to be in reality a deep groove between two projecting folds of mucous membrane. The sides of this fold were partly stripped of epithelium, and its floor was broken through so as to lead into a minute cavity in the sub-mucosa crammed with leucocytes and containing clusters of cocci. On the surface of the epithelium there were but few micro-organisms. 2. The *sub-epithelial tissue* near the rupture and below it was much damaged and had to some extent lost its staining power. It consisted for the most part of unstriped muscle in a markedly dissociated state, with a few compound racemose glands, and numerous veins which were strikingly large and for the most part collapsed and empty. Here and there, however, one was seen to contain an organised thrombus containing round mononuclear elements and fibroblasts. There was also diffuse leucocytic infiltration. 3. The muscular coats, longitudinal and circular, were quite thick and well developed. The individual bundles were somewhat loosely compacted, as though they had undergone partial dissociation. Towards the edge of the rupture their outlines became less distinct and faded away amidst masses of multifarious micro-organisms. In both the muscular layers were sinuous tracks crammed with polynuclear elements amongst which spherical and elongated masses of cocci were readily demonstrated in preparations stained by Gram's method (Czaplewski's modification), after previous treatment with lithiocarmine and differentiation in acidulated alcohol. In the bundles of circular muscle, which were of course divided longitudinally on the transverse section of the gullet, patches free from nuclei and presenting a hyaline-degenerate appearance, were here and there detected. 4. The outer fibrous coat contained adipose tissue in small amount, whilst a few nerve-fibres and an occasional ganglionic cell were seen. Its outer surface where it had been in contact with the extravasated gastric contents was quite necrotic and swarmed with various bacterial forms. The nuclei had lost their staining power. The inner part adjacent to the longitudinal muscle coat was in a state of intense leucocytic infiltration and contained numerous colonies of cocci. Other forms of bacteria were not seen. Here were also many large veins, most of them quite solidly thrombosed, the process being of recent date, as was evidenced by the outline of the red discs being still visible. Organisation was, however, in progress, as was evidenced by the presence of mononuclear elements and fibroblasts. Immediately outside these veins were numerous polynuclear leucocytes and cocci. The general impression produced by a study of these sections was that whilst the outside of the gullet and the sides of the rupture were gangrenous and swarmed with the multifarious organisms derived from the gastric contents with which they had been in contact, the deeper parts of the gullet wall were in a state of purulent inflammation owing to their invasion by pus-cocci. There was also a thrombo-phlebitis of the œsophageal veins which, however, could not have been septic in the first instance. Had it been so organisation would hardly have occurred. I cannot look upon either the thrombo-phlebitis or the purulent infiltration as having developed during the few hours that elapsed between the occurrence of rupture and the termination of life. The loss of epithelium and of staining-power and the dissociation of the submucous structures may be interpreted as evidence of a process of intra-vital digestion. Considering, however, the fact that 40 hours elapsed before the necropsy was made, it would not perhaps be justifiable to attribute these changes to other than post-mortem alteration.

PREVIOUS RECORDS.

In searching the records it is important to exclude cases in which the œsophagus has been perforated—(*a*) from within by foreign bodies, such as bones, false teeth, &c., or by bougies, probangs, and the like introduced for diagnostic or therapeutic purposes, or by ulceration,[2] malignant or otherwise; and (*b*) from without, by the erosion of aneurysms, adherent masses of caseous glands, tumours, and the like. The possibility of the occurrence of post-mortem digestion and of agonal œsophago-malacia has also to be borne in mind, and the appearances so produced carefully distinguished from the results of sudden rupture taking place *intra vitam*. Failure to appreciate this distinction is responsible for several erroneous records.[3] Eliminating these faulty observations, there remain 17 indubitable and more or less carefully observed cases of rupture of an apparently healthy gullet. In the appended table I have endeavoured to bring out the salient features of these 17 cases, so far as I have been able to collate them.

The first of these observations, and in some respects the most interesting, was made by the illustrious Boerhaave, who published a full account of it in Latin. His patient was the celebrated Dutch Admiral Baron Wassenaer, and the following is an abstract of Boerhaave's description, which from its fulness and scientific minuteness may well be looked upon as classical. (Case 1 in table.) The baron, a man about 50 years of age, moved in the best society of Holland, and was a diner-out and a large eater, though not a heavy drinker. After meals he used to feel a disagreeable sensation in the cardiac region of the stomach and obtained relief by the use of emetics. On the day of his attack, being in the best of health, the baron partook at his early dinner of the following substantial repast: Veal soup with herbs, boiled lamb with cabbage, fried sweetbread and spinach, a duck, two larks, and a compôte of apples. For dessert he had pears and grapes, followed by sweetmeats. His beverages were beer and moselle. Afterwards he went out riding and on his return, feeling uncomfortable in the epigastrium, he took three cups of hot *thistle tea* to induce vomiting; but with poor success. He then drank four cups more of the same decoction, and whilst straining violently in his efforts to vomit he was suddenly seized with a terrible pain and shrieked aloud so that his servants rushed to his assistance. He exclaimed that something had given way in his stomach and

[2] In excluding cases of ulcer it is important to remember that the mere solution of continuity due to rupture is liable to be described as an "ulcer." Compare the case of Lindemann and that of Lindsay and Lorrain-Smith.

TABLE OF 17 CASES OF RUPTURE OF THE APPARENTLY HEALTHY ŒSOPHAGUS.

No. of case.	Sex and age.	Alcoholic.	Previous history.	Onset.	Symptoms.	Emphysema.	Duration of life in hours.	Shape and position of rupture.	Results as determined by necropsy.	Authority and date.
1	Male, over 50.	?	Gouty; heavy eater; accustomed to use emetics.	Sudden, whilst retching.	Felt something give way; intense pain; collapse; typical situs; dyspnœa.	Yes.	18	Complete transverse rent three fingers' breadth above the diaphragm.	Collapse of the lungs; air and gastric contents (104 oz.) in both pleural cavities.	Boerhaave,[1] 1724.
2	Male, ? age.	Yes.	"Debauch" the previous night.	Sudden, after drinking hot water to induce vomiting.	Felt something give way; slight hæmatemesis; severe pain; dyspnœa; collapse.	"	About 12	Longitudinal slit just above the diaphragm big enough to admit two fingers.	Double pneumothorax; gastric contents in both pleural cavities.	Dryden,[2] 1787.
3	Male, 24.	"	Severe epigastric pain and vomiting for several months.	Sudden, after public dinner, during vomiting.	Slight vomiting; severe epigastric pain; typical situs.	"	14	Large rent just above the diaphragm.	"Portions of food in the lower part of the chest."	Wilkinson King,[3] 1843.
4	Male, 38.	"	"Took lye when a child and since then food has stuck near pit of stomach."	Sudden, after attempting to swallow a sausage which became impacted and caused straining.	After striving to vomit, some hæmatemesis; pain; oppression; dyspnœa; typical situs.	"	50	Gaping rent one and a quarter inches long by three-eighths of an inch wide three inches above the cardia; edges sharply defined.	Gangrenous cavity in the posterior mediastinum; "exudation" in both pleural cavities.	Meyer,[4] 1858.
5	Male, 35.	...	Gastric disturbance six weeks previously when a bone was thought to have been swallowed.	Sudden, after carouse.	Vomiting at first, then pain; dyspnœa; collapse; typical situs.	"	11½	Longitudinal tear five centimetres long, encroaching on the stomach.	Double pneumothorax; six to eight ounces of reddish fluid containing solids and fat in each pleural cavity; gangrenous cavity in the mediastinum.	Gramatzki,[5] 1867.
6	Male, 49.	? Probably.	—	Sudden, after meal of ducks, green peas, and plum-pudding.	Felt something give way during vomiting; pain; dyspnœa; collapse; died asphyxiated.	"	16	Longitudinal slit one inch long just above the diaphragm.	Three quarts of fluid containing food in the left pleural cavity; lung collapsed.	Griffin,[6] 1869.
7	Male, 35.	Yes.	Drinking hard for several days before onset; from infancy had some dysphagia.	Sudden, after vomiting and whilst exercising a horse.	Felt something give way; pain; dyspnœa; intense thirst; collapse.	Not stated.	7½	Slit one and a half inches long in the left side of the lowest part of the gullet, extending further in the mucous than in the other coats; edges well defined above; irregular and softened below.	Gangrenous cavity in the posterior mediastinum opening into the left pleural cavity, which contained two quarts of fluid containing starch and oil; lung collapsed.	Charles,[7] 1870.
8	Male, 31.	"	Repeated attacks of gastritis; delirium tremens; hæmatemesis.	Sudden, during violent efforts to dislodge a piece of meat impacted in œsophagus.	Pain and dyspnœa, not very prominent at first; fever.	Yes.	180	Rent two inches long at the level of the bifurcation of the trachea.	Cavity in the right side of the posterior mediastinum crossed by fibrous bands and filled with clot; overlying pleura adherent.	Fitz,[8] 1877.
9	Male, 17.	No.	Attack of blood-poisoning a short time previously.	Sudden, during vomiting.	Hæmatemesis: intense feeling of suffocation; pain; collapse.	Stated to have been present before date of rupture; but?	4	Rent 1·5 centimetres long at one inch above the cardia.	Opened into the left pleural cavity, which contained gastric contents.	Taendler,[9] 1878.
10	Male, 53.	"	Dyspeptic for many years with occasional vomiting.	Sudden, after feeling unwell for two hours after dinner.	Severe pain in the left side and shoulder; collapse.	Not stated.	7	In posterior wall of the gullet one and a half inches long just above the diaphragm; through the mucous and submucous coats only above.	—	Adams,[10] 1878.

TABLE OF 17 CASES OF RUPTURE OF THE APPARENTLY HEALTHY ŒSOPHAGUS—(*Continued*).

No. of case.	Sex and age.	Alcoholic.	Previous history.	Onset.	Symptoms.	Emphysema.	Duration of life in hours.	Shape and position of rupture.	Results as determined by necropsy.	Authority and date.
11	Male, 48.	?	Chronic gastric ulcer.	Sudden.	Vomiting, followed by pain and collapse.	No.	15	"Ulcer" two centimetres long by one centimetre wide in the posterior wall of the gullet two centimetres above the cardia and a little to the right; edges thickened, somewhat funnel-shaped.	Double pneumothorax; food in both pleural cavities; infiltration of the posterior mediastinum with gastric contents.	Lindemann,[11] 1887.
12	Male, 32.	No.	"Good eater; drank little."	Sudden attack of nausea causing the patient to tickle the fauces with his finger; during retching agonising pain and sensation of something having given way.	Pain; collapse; cyanosis.	Yes.	"A few."	Clean tear one centimetre long just above the cardia.	Left pleural cavity full of gas and food.	Wolff,[12] 1894.
13	Male, 47.	No.	Vomiting; dyspeptic.	Sudden, whilst vomiting.	Pain; collapse; dyspnœa; voice higher pitched than usual; disappearance of cardiac dulness.	Yes.	13½	Sharply defined rent one and a half inches long immediately above the cardia.	Left pneumothorax; in each pleural cavity was a pint of grumous fluid like gastric contents.	Harrison,[13] 1893.
14	Male, 59.	Yes.	Drinking hard for a week previously to admission.	Sudden.	Pain; dyspnœa; effusion into the left pleural cavity.	Yes.	37	Sharply defined "ulcer" one and a half inches long two inches above the cardia, involving the mucous membrane only below.	Accumulation in the posterior mediastinum, bursting into the lung but not communicating with the pleural cavity; gas in the mediastinum; acute pleurisy on both sides.	Lindsay and Lorrain Smith,[14] 1899.
15	Male, 43.	?	"Quite healthy."	Sudden; illness and vomiting after eating.	Collapse.	?	6	Rent two centimetres long in the gullet six centimetres above the cardia.	Food in the left pleural cavity.	Heintze,[15] 1900.
16	Female, 62.	No.	?	Sudden, after vomiting induced by salt and water.	Intense epigastric pain aggravated by swallowing; dyspnœa; collapse.	Yes.	22½	Rent five-eighths of an inch long one and a half inches above the diaphragm.	Lower part of the gullet was much softened; brownish fluid in the posterior mediastinum and the left pleural cavity; collapse of the left lung.	Bowles and Turner,[16] 1900.
17	Male, 40.	Yes.	"Drunk every night for 20 years;" much addicted to retching.	Sudden, probably during retching.	Pain not the most prominent symptom; intense dyspnœa; cyanosis; collapse.	Yes.	About 10	Slit-like rent 1·5 centimetres long in the anterior surface of the gullet just above the diaphragm, prolonged into the stomach by a fissure in the mucosa.	Contents of the stomach in the posterior mediastinum and the left pleural cavity; collapse of the left lung; acute pleurisy of the back of the right lung; gas in the mediastinum and the pericardium.	McWeeney, 1900.

that he felt sure he must die at once. In a cold perspiration and ghastly pale he was taken to bed and the nearest medical man was sent for who resorted to friction with warm cloths, administration of mucilaginous drinks, olive oil, and poultices. There was no more vomiting and everything taken was retained. Boerhaave, who then came on the scene, found the patient complaining only of an intense pain in the epigastrium much increased by eructation and by movements of the spinal column. He was sitting up in bed with his body bent forward almost doubled in two. There was no nausea, no difficulty in swallowing, no hiccough, and no abdominal tenderness. The patient's mind was quite clear, and he assured Boerhaave that some change must have taken place in the position of parts within the chest. Diagnosis was impossible, and the measures resorted to—hot fomentations, venesection, &c.—were unavailing to give the slightest relief. Very little urine was passed despite the large amount of fluids swallowed. After a night of the most intense agony, dyspnœa began to come on; the pulse began to fail about 3 o'clock in the following afternoon, and death supervened at 5 o'clock. 24 hours afterwards Boerhaave made the necropsy. He found extensive subcutaneous emphysema, the heart normal, and both lungs collapsed. The pleural cavities contained 104 ounces of fluid, consisting for the most part of what had been taken by the patient during the last hours of life. The material smelt of roast duck. On the pleura covering the œsophagus was a flabby blackish spot about three inches in diameter in the centre of which was a rent one and a half inches long by about a third of an inch wide, from which fluid similar to that in the pleural cavities could be squeezed, and which communicated with the lumen of the gullet. This was found to have been ruptured and the two ends retracted in opposite directions. The most careful examination failed to reveal the existence of any ulcerative or other morbid process in the coats of the gullet which appeared quite healthy. The stomach and intestines were distended with gas but otherwise normal.

This case recorded by Boerhaave is unique in presenting a complete transverse division of the gullet. Its rapid course and severe symptoms are in harmony with what is usually observed. Fitz's case (Case 8 in the table), on the other hand, lasted no less than seven and a half days, and as the observation has been very carefully and fully recorded by its author, who was at that time assistant professor of pathology at Harvard, it may properly be abstracted in this place. The patient, a merchant, aged 31 years, was in a debilitated condition from over-indulgence in alcohol, and suffered from gastritis and hæmatemesis. For years he was in the habit of cutting his food into small pieces, and he ate slowly, but never complained of pain or difficulty in swallowing. Whilst at supper a morsel of food lodged in his gullet, and it was only after an hour of great discomfort that he succeeded in ejecting the substance, which proved to be a piece of gristly meat nearly circular in shape, about an inch in length and rather more than half an inch in diameter. It came from his mouth with noise and force as if propelled from a popgun; he sank back exhausted and ejected a moderate quantity of clotted and liquid blood. A swelling was then noticed at the angle of the lower jaw on each side (emphysema). In the subsequent progress of the case but little pain was complained of till the sixth day, when it became sharp and excruciating and was accompanied by tonic spasms of the flexor muscles of the limbs. Swallowing and vomiting could both be quite well performed. Respiration was likewise not interfered with until the last day of life. Emphysema was extremely pronounced; the whole subcutaneous tissue of the body appeared to be undergoing a process of inflation. The face, the eyelids, the upper part of the chest in front, and the entire back were swollen; the scrotum was enormously distended and the inflation extended to the middle of the thighs. At the necropsy Dr. Fitz found the anterior mediastinum to be emphysematous, independently of the conditions produced on removal of the sternum. The left pleural cavity was obliterated by old adhesions which were emphysematous and the costal pleura contained numerous bullæ distended with air. The lungs were œdematous and the lower lobes were moderately collapsed. In front and to the right, at and below the bifurcation of the trachea was found a longitudinal rupture of the œsophagus two inches in length extending through all its coats. Its edges were sharply defined and gave no evidence microscopically or otherwise of a pre-existing ulcerative or degenerative process. A communication was thus established between the œsophagus and mediastinum in all directions and behind the former to a limited extent. This cavity was of the volume of a small lemon, was crossed by fibrous trabeculæ, and was filled with clotted blood. Its walls, neither soft nor pulpy, were of greenish hue, and the thickened and reddened left pneumogastric nerve could be seen projecting behind. The tissues of the posterior mediastinum on the left side were spongy and stained with blood. The pleura covering the cavity mentioned on the right side was adherent to the opposed upper lobe of the lung, the adhesions being recent, discoloured, and offensive. The inner surface of the œsophagus, from the bifurcation of the trachea to the cardiac orifice of the stomach, was of a greenish colour. Its epithelium was slightly flocculent, occasionally thickened in patches, and was entirely absent over a space an inch in diameter below the rent, the exposed surface being smooth and shining; its walls were of normal consistence. The appearances presented by the stomach were those of chronic gastritis and there was no indication of post-mortem softening.

To the cases of undoubted rupture of the œsophagus (17 in number) which have been sufficiently recorded for inclusion in the table, there must be added, as almost certainly belonging to this category yet not recounted in sufficient detail for tabulation, the cases of Williams[4] (1848), Oppolzer[5] (1851), Bailey[6] (1873), and Heyfelder.[7] A case recorded as rupture of the œsophagus by Colegrove,[8] the account of which is not accessible to me, seems to have escaped the notice of Fitz, who, writing in America, might have been expected to have come across it in his review of the literature.

The subject has been discussed and the literature up to date collected by my friend and colleague on the examining board of the Royal University, Professor Charles of Queen's College, Cork, in 1870. This was in connexion with a study of the case that came under his own notice. In 1877 Fitz published the case above abstracted, which was under the care of Dr. Adams of Baltimore. Fitz also took occasion to collect the literature up to date and discussed it very ably, though I cannot agree with him in his exclusion of several records which appear to me to be genuine cases of intra-vital rupture, such as those of Boerhaave (Case 1 in table), Dryden (Case 2), King (Case 3), and Charles (Case 7). Dr. John Knott of Dublin has also treated of the subject in a very admirable way in an "Essay on the Pathology of the Œsophagus," which gained the gold medal of the Dublin Pathological Society at the close of the session of 1877. There is, further, a full notice of the accident and a discussion of its distinction from agonal and post-mortem œsophago-malacia in Zenker and von Ziemssen's "Cyclopædia of Medicine."[9] Finally, Sir Morell Mackenzie has dealt with the subject in his work on "Diseases of the Nose and Throat," and extended our knowledge by a series of experiments the outcome of which I shall return to later.

A number of cases described or quoted as examples of this condition prove on examination to be examples of agonal or post-mortem œsophago-malacia. Details of such up to 1877 will be found in the work of Fitz and that of Zenker and von Ziemssen, and references to some of these have already been given here. In collating the records I have considered it necessary to eliminate two cases published by Stanley Boyd.[10] One was that of a child, aged four months, who had been suffering from high fever and quick pulse, with an erysipelatous rash. Difficulty in breathing came on two hours before death. There was no emphysema. At the necropsy an aperture two millimetres in diameter was found midway between the bifurcation of the trachea and the cardia. For a short distance above and below it the circular muscle fibres were exposed between two separated longitudinal bands. Except for several narrow clots about an inch long, lying in furrows between the longitudinal folds, no morbid change was detected in the

[10] Transactions of the Pathological Society of London, vol. xxxiii., p. 123.

gullet. At the necropsy extravasation of gastric contents is not mentioned. The left pleural cavity was normal; the right contained an ounce of bloody fluid; the lungs were not collapsed. The committee (Dr. J. F. Goodhart and Mr. H. T. Butlin) to which the specimen was referred reported on it as a case of "gastric solution," and from the age of the patient, her previous illness, and the absence of emphysema and of extravasation of gastric contents, I have little doubt that the case was an example of agonal œsophagomalacia.

Boyd's second case was that of a girl, aged 18 years, who was the subject of Addison's disease and who had suffered from persistent vomiting for several months. There was no sudden pain, no pneumothorax, no emphysema, and no dyspnœa. At the necropsy there was a longitudinal rent five centimetres long in the left side of the œsophagus immediately above the cardia; part of the overlying pleura had disappeared, and "this must have been due to digestion." The stomach showed some deep circular erosions and black lines marking the course of the vessels. The same committee reported on this specimen also and found that "the mucous membrane at the level of the opening was dark and thickened as if from pre-existing disease, but the slit-like character of the opening and an uneven furrow between the longitudinal rugæ parallel to it are suggestive of gastric solution. But it seems probable that the œsophagus had been weakened by pre-existing disease and gastric solution, or both together, and had given way during the last few hours of life, and we think the specimen may serve to call attention to the occurrence of gastric solution during the enfeeblement immediately preceding death—an occurrence which is probably not very uncommon, which has never yet been adequately described, and which has produced within our knowledge most puzzling appearances." These reports manifestly place the cases in question outside the category of spontaneous rupture of the apparently healthy œsophagus. On the other hand one meets with cases described under the name of ulcer which undoubtedly belong to the category now under notice. Lindemann's (Case 11 in table) is one of these, and the case reported by Professor J. A. Lindsay and Professor Lorrain Smith (Case 14) is another. To the courtesy of Dr. Lorrain Smith I am indebted for an opportunity of examining the specimen, which is preserved in the pathological collection at the Queen's College, Belfast, and have been able to convince myself that it is of a similar nature to my own. A solution of continuity in the wall of any tubular viscus is by many pathologists termed an "ulcer," especially when gaping of the sides of the rent suggests loss of substance.

General Features of the Cases.

Sex.—Of the 17 cases 16 were those of men: one of the non-tabulated cases (Oppolzer's) was that of a woman.

Age.—The subjects were mostly men in the prime of life, the average age of those of whom it is recorded being 42 years.

Alcoholism.—This seems to be a pre-disposing cause, and in eight of the 17 cases there is a distinct history of excessive drinking.

Vomiting.—In eight of the cases this was of frequent occurrence, whether the result of excessive eating or drinking or induced by emetics. It is, however, as an exciting cause that vomiting is especially prominent in connexion with rupture of the œsophagus, for in every one of the cases tabulated the accident seems to have occurred either during vomiting or whilst the patient was straining to accomplish the act (retching).

Symptoms.—In a number of the cases there was a distinct feeling that something had given way within, and in all there was pain, usually of the most agonising character, speedily followed by collapse and nearly always associated with dyspnœa. The position adopted by the sufferer was characteristic—sitting up with the trunk stooped forward as much as possible. The pain was usually aggravated by swallowing and sometimes by eructation. The most striking of all the symptoms and one of the most constant is emphysema. It appears first in the neck spreading up to the face, causing more or less obliteration of the features, and downwards over the trunk, reaching to the scrotum and thighs. The symptom was present in 12 of the cases and probably in several of the others, but the records of some of these are imperfect [Adams (Case 10 in table), Taendler (Case 9), and Heintze (Case 15.] These characters make up an extremely well-marked and very unusual clinical picture, which, once seen, is indelibly imprinted on the recollection.

Duration of life.—Fitz's case (Case 8 in table) survived by far the longest—seven and a half days. The other 15 cases in which the duration is stated lasted on an average only 17 hours.

Position and shape of rupture.—In all the cases save that of Fitz, the opening was immediately above the diaphragm, and was often prolonged upwards or downwards by a sort of fissure in the mucous membrane. This feature was especially well marked in my case. Save in the case of Boerhaave (Case 1 in table) the shape of the rupture was a longitudinal slit opening usually into the left pleural cavity, sometimes into both, occasionally (Lindsay and Lorrain Smith, Case 14 in table) into neither.

Etiology.—Charles in his very able paper[11] considers that "the rupture followed softening which may have resulted from chronic inflammation of the stomach and lower third of the œsophagus. The continued ingestion of alcohol probably induced a chronic gastritis or gastro-enteritis, the inflammation involving also the lower third of the œsophagus. Softening of the mucous membrane occurred as a consequence. ..... Immediately preceding or accompanying the vomiting there may have been temporary spasm of this tube resembling the 'hour-glass' contraction of the uterus, and under these circumstances the contents would be impelled against its parietes close to the cardiac orifice." This view is practically identical with that subsequently adopted by Zenker and von Ziemssen. Fitz[12] considers that "two factors are essential—the impaction of a foreign body in the œsophagus and the exercise of great muscular force in the attempts to remove it." This opinion is manifestly incorrect, inasmuch as the factors in question were present only in two of the cases—that of Meyer (Case 4 in table) and his own.

A much better grounded opinion is that of Zenker and von Ziemssen[13] who look upon rupture as the consequence of a digestive softening of the œsophagus occurring *intra vitam* in persons who are quite well otherwise. They lay down the following conditions as pre-requisite for the production of the softening: (1) regurgitation of stomach contents rich in pepsin and acid; (2) protracted retention of regurgitated food in the œsophagus; and (3) cessation or great weakness of the circulation. The first of these conditions occurs when the stomach is over-distended, or in association with attempts at vomiting. The protracted retention would be realised if there were diminished muscular energy in the œsophagus such as might readily be occasioned by the exhaustion due to continuous and violent vomiting. The local circulatory disturbance is harder to account for. Zenker and von Ziemssen think that the œsophagus, on account of its much less abundant blood-supply, is proportionally less protected against the gastric juice than the stomach, and, as regards the nature of the disturbance the authors reject infarction and embolism, curiously enough omitting to mention thrombosis, which, in view of the frequency of varicose veins in the lower part of the gullet, seems the most probable cause. They speak of a "spastic ischæmia" and conclude as follows: "And hence, accepting Andral's witty remark that in consequence of varied emotions the stomach, quite as well as the skin, may now turn pale and now be suffused, we shall certainly ask whether the striking pallor of the face and lips during vomiting does not extend to the stomach and œsophagus. This ischæmia may not ordinarily extend to a degree where the tissues would be exposed to the action of the gastric juice, but an unwonted increase in the same would open the door for a catastrophe. After all we have said we hold that the view is well founded that all cases of spontaneous rupture of the œsophagus may be referred to an intra-vital œsophago-malacia."

Mackenzie considers that the immediate cause of rupture is vomiting, and that "vomiting only causes rupture when the contents of the stomach cannot be expelled through the gullet at the same rate that they leave the viscus. ..... It is probable that some temporary obstruction near the upper end of the gullet preventing the flow of fluid matters from the stomach is the essential feature in rupture." He then points out that "to determine the cause of this obstruction is not always possible. In two cases, as already remarked, a foreign body was impacted in the œsophagus, but these were

[11] Loc. cit. [12] Loc. cit. p. 34.
[13] Loc. cit., vol. viii., p. 106.

exceptions. In all the others the obstruction, if present, must have been due to something inherent in the tube itself. This is probably to be found in strong contraction of the circular fibres of the gullet at the upper part of the œsophagus. In two cases—those of Fitz (Case 8 in table), and of Wilkinson King (Case 3)—there was tetanic spasm, affecting in the one the flexors of the limbs and in the other the abdominal muscles; and it need hardly be pointed out that if such a condition existed at the same time in the muscular walls of the gullet rupture would be likely to take place." In writing the above Mackenzie must have forgotten that the cramp did not come on till long after the occurrence of the rupture—on the seventh day of the illness in Fitz's case, and after the onset of pain and dyspnœa in that of Wilkinson King. Mackenzie endeavoured to found his view on a basis of experiment by testing a number of normal gullets removed post mortem in order to find out at what point and in what manner they underwent rupture when overstrained by excessive pressure from within. He concluded (1) that rupture by direct pressure applied within the œsophagus always takes place in a longitudinal direction; (2) that the rent never occurs in the upper part of the tube and in most cases is confined to the lower third; and (3) that the mucous membrane offers greater resistance to strain than the muscular covering.

Before dismissing from our attention the valuable work of Mackenzie on this subject, it is only right to say that, in rejecting the auto-digestion theory of Zenker and von Ziemssen, he has quite failed to grasp the exact nature of their position. He quotes them as considering that the accident results chiefly from "intra-mortem œsophageal malacia," or softening of the coats from peptic solution in the last hours of life. But the German authors distinctly lay down[14] "that œsophago-malacia may be developed in rare cases *intra vitam* in a patient who is perfectly well, without any connexion with any preceding serious disease, and form the basis of the so-called spontaneous rupture of the œsophagus."

That intra-vital digestion is not the sole cause is clearly proved by the uniformly longitudinal form of the aperture and its sharply-defined edges—characters which are just the opposite of those met with in gastro-malacia. That pressure from within cannot be the sole cause is, I think, evident from the exceeding rarity of the accident despite the frequency with which the œsophagus is distended by relatively enormous foreign bodies.

The conclusion to which I have arrived as the result of a careful study of existing data is, that the two main factors that are operative in causing rupture of the macroscopically normal gullet are (*a*) softening of the coats and (*b*) sudden increase of pressure from within. The softening is due partly to intra-vital digestion, and partly (at least in the case which I observed) to inflammatory infiltration. The intra-vital digestion is to be accounted for by (*a*) circulatory disturbance, which in my case took the form of venous thrombosis, and (*b*) prolonged sojourn of peptic matters in the gullet from prolonged retching. The increased pressure from within is doubtless ascribable to the violent propulsion of the gastric contents into the lower part of the gullet whilst its upper outlet is obstructed by the contracted state of the muscle—in other words to want of coördination of the muscular action of the tube, probably due to exhaustion from prolonged over-activity. Whether a localised phlegmonous œsophagitis—for that is the condition which existed in the case now recorded—is a constant factor in these cases, it is of course impossible to assert in the absence of microscopical details of the other cases. I believe I may lay claim to be the first to establish the existence of this condition as a possible cause of rupture of the apparently healthy gullet.

Dublin.

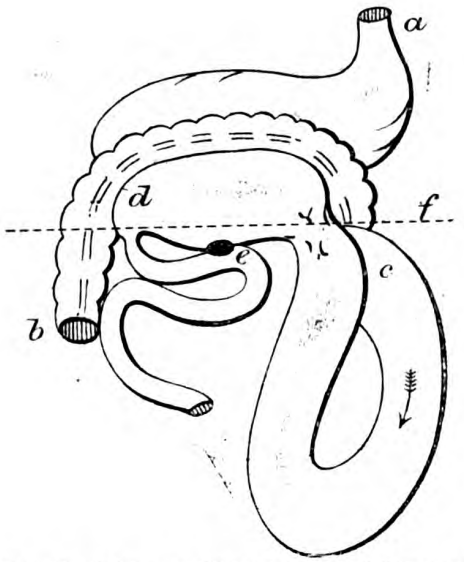
BATH MINERAL WATER HOSPITAL.—At the meeting of the committee of this institution held last week it was decided to make alterations and improvements in the hospital at a cost of upwards of £5000. Our commissioner's strictures seem to have had a good effect.

THE Professor of Physiology in Tübingen, Dr. Willy Kühne, who died last month, left directions that his body was to be cremated and that during the process the first movement of Beethoven's Ninth Symphony was to be performed; also that no memorial festival should be held.

A CASE OF PERNICIOUS ANÆMIA FOLLOWING ON TRAUMATIC STRICTURE OF THE SMALL INTESTINE.

BY ARTHUR E. BARKER, F.R.C.S. ENG. & IREL.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

(With Pathological Report by W. Hunter, M.D.)



A CAREFUL perusal of Dr. William Hunter's most suggestive essays on pernicious anæmia has convinced me that the following case ought to be put on record. I do not feel competent to pronounce on the general questions which this writer so ably raises, but the case appears to me to lend strong support to his views as far as it goes. It has also some points of intrinsic surgical interest and especially the effect of cart-wheel accidents upon the intestine short of actual rupture. The notes and observations on the blood, &c., were accurately kept by my house surgeon, Dr. F. H. Thiele, whose abstract of them forms the basis of this record. Dr. Hunter has also kindly added a report on his study of specimens obtained at the post-mortem examination which adds great interest to the case.

A man, aged 28 years, a sawyer, was admitted into University College Hospital on Feb. 5th, 1900. He had always enjoyed good health until seven years ago when he was run over by a loaded wagon. The two near wheels, which were broad, passed over the lower part of the thorax, breaking, it is stated, five ribs and splintering another. This was followed by "pleurisy and inflammation." He was ill for 14 weeks, and after this began to have the attacks now complained of. There was no history of syphilis, rheumatic fever, or tumours, but the patient had always suffered from "heartburn," which had been worse since the accident. The patient had always been quite temperate. He had been well fed and had lived among healthy surroundings.

On admission he was noted as being very well nourished, inclining to fat, but extremely anæmic. This was most marked in the conjunctivæ, lips, and finger-nails. An examination of the abdomen revealed no abnormality of the internal organs and only a slight tenderness and increased resistance midway between the right iliac spine and the navel. Nothing unusual could be felt from or in the rectum. His reason for seeking treatment now was extreme weakness and anæmia with periodic attacks of pain and vomiting which set in soon after the accident seven years ago. These had occurred at intervals of from a week to a month and lasted from a week to a fortnight. During these attacks pain and swelling began about two inches to the right and below the umbilicus and spread from there all over the abdomen. At the same time the patient had vomiting and diarrhœa. The vomit consisted of food and green fluid which tasted bitter and sour. The motions during these attacks were much lighter in colour than usual, and sometimes very pale indeed. The pain was much relieved by change of posture in any direction. The great pallor was first noticed in the summer of 1899, and since September, 1899, the patient had suffered from shortness of breath on exertion accompanied by palpitations. During and after September, 1899, the patient was prevented from working for about 10 weeks by vomiting and diarrhœa. On admission the temperature was 99·4° F. and the pulse was 112. This was about the average for nearly a week, when the fever slightly increased to about 100° or a little over this. He then (Feb. 17th) had the first attack of pain since admission. It began at the point described and spread all over the abdomen, lasting about one and a half hours. He vomited at this time both food and bile, and had a loose stool without any undigested food or fat and not offensive. Dr. Thiele's analysis of the blood showed red corpuscles 2,000,000, white 54,000, and hæmoglobin 30 per cent. The optic discs were now examined and were found to be normal. On Feb. 16th the stomach was washed out, but showed nothing abnormal. On the 17th a hæmorrhage was noticed in the left eye above and to the outer side of the optic disc. Pain and vomiting occurred on the previous night. The vomited matter was bile-stained with very little undigested food. It contained free hydrochloric acid. Reduced iron was now

given. The diet was full and was eaten with appetite except in the morning. The patient was growing paler. On the 21st he vomited twice with but little pain. The urine had been free from albumin since admission. It was acid and of normal colour with an excess of indican. Urea 2·5 per cent. There had been no loss of flesh, but the pallor was increasing very much and severe headache had been complained of for some days. On the same day (the 21st) an examination of the blood showed red corpuscles 1,000,000, hæmoglobin 20 per cent., and white corpuscles 1 : 450. The blood itself to the naked eye was very thin and watery; megalocytes and microcytes, but no nucleated red corpuscles, were seen. Feeling now satisfied that there was some serious lesion high up in the small bowel, probably of the nature of a stricture, I decided to explore the abdomen.

Operation was performed on Feb. 22nd. The abdomen was opened in the mid-line above the umbilicus. The first thing noticed was a coil of enormously distended and thickened small intestine of white colour, which for the moment was taken to be the stomach. It was seen, however, on nearer inspection to lie below the colon, but to overlap it above. The distension terminated to the right of the spine in a sharp kink among many old smooth adhesions,

a, Stomach. *b*, Colon. *c*, Dilated jejunum, coil 7 ft. long. *d*, Dilated jejunum above stricture. *e*, Anastomosis between dilated and healthy jejunum. *f*, Obvious course of cart-wheel.

and below this the intestine was normal and empty. On pushing the finger into the distended coil so as to invaginate it a narrow stricture could be felt at the kinked spot. To the left the dilated coil was held down to the spine by adhesions which led me to the conclusion that I was dealing with the first part of the jejunum as it emerged from under the plica. These adhesions, too, were all smooth and evidently old. I now anastomosed the distended loop with the empty portion below the kink and stricture. This was done by a double row of silk sutures in the usual way. In making the openings in the contiguous loops the contrast between the thick-walled upper portion and the thin-walled normal viscus below was very striking. The abdomen was now closed in with silk sutures. The operation lasted 50 minutes and towards the end the condition of the patient was not very good. On this account a pint of normal saline solution was injected hypodermically during its concluding stages. After the operation there was a good deal of pain which was relieved by morphia, after which the patient fell asleep. The pulse was 116, the temperature was 102·2°, and the respiration was 38. The next morning he was not so well. The temperature was 102·8° and the pulse was 136. Death took place at 5.15 on the 24th.

The condition of things at the post-mortem examination was most instructive. The anastomosis left nothing to be desired as to water-tightness. Union was sound as tested in various ways and there was no peritonitis. The point of anastomosis lay in front of the spine nearly in the middle line. It united an enormously distended and thick-walled loop of small intestine with an empty coil lying below it. The cause of the distension was seen to be a tight stricture of the gut lying just to the right of the spinal column below the transverse colon, where the small intestine was kinked on itself as well. This kink was glued to the spinal column by many adhesions of old date. To the left of the spine the dilated coil was similarly held down by adhesions close to the termination of the duodenum. This had given the wrong impression at the operation that the distended coil was the first foot or so of the jejunum as it emerged from under the fold containing the mesenteric artery. On further examination now it was seen that the point glued by adhesions to the spine corresponded to a spot about seven feet below the commencement of the jejunum and that the whole of the left side of the abdomen was filled by a very much dilated and thick-walled coil of the latter some seven feet long. This coil was distended to about the size of an adult forearm with pale yellow fluid which was only escaping slowly through the anastomosis into the healthy bowel below (*vide* diagram). The crushing injury from the cart-wheel had also caused adhesions between the transverse colon and adjacent small intestine and had destroyed the upper end of the right kidney which was converted into a fibrous mass. The second part of the duodenum had also been damaged by the wheel. Its serous coat had been cracked in places, leaving the muscular coat exposed. These patches were glazed over and healed but stood out clearly against the normal bowel. The cracks reminded one of what is seen in cases of intussusception where the serous coat gives way, but I had never before had an opportunity of seeing such a crack healed. It was seen in this case that such a lesion could be repaired without the muscular coat adhering to any surrounding organ. The liver as tested by Dr. W. Hunter, who was present, contained a large excess of iron. On opening the distended bowel the stricture was found to be due to the contraction of an ulcer produced by the crushing of the mucous membrane where the cartwheel caught it against the spine. It was annular and the lumen was only about the size of a cedar pencil. Other healed ulcers were seen above it and some partially healed. The seven feet of bowel between the stricture and the duodenum were enormously dilated and full of pale yellow fluid like thin custard. This was taken away by Dr. Hunter for analysis. On examining the mouth and nose the ethmoidal sinuses were found to be full of pus. In all these factors the conditions were present which Dr. Hunter believes to be at the root of pernicious anæmia—suppuration connected with the mouth, a stricture of the intestine retaining the contents long enough to ensure their decomposition, and the formation of a specific poison.

The cause of death was probably the escape of the poison through the anastomosis and its rapid absorption by the previously healthy and empty intestine as indicated by high temperature and rapid pulse. One can only regret that no opportunity had been given for the performance of the same operation some months earlier before the patient had become so profoundly overcome by the disease.

Pathological Report.

BY WILLIAM HUNTER, M.D. EDIN., F.R.C.P. LOND.,
JOINT LECTURER ON PRACTICAL MEDICINE, CHARING CROSS HOSPITAL
SENIOR ASSISTANT PHYSICIAN, LONDON FEVER HOSPITAL.

I am indebted to Mr. Barker for the opportunity of seeing the case above described, which has proved to be one of especial interest in relation to the pathology of pernicious anæmia. I only saw the patient a few hours before his death when he was too ill to be thoroughly examined. Nevertheless, from the account of his illness, his appearance, the degree of oligocythæmia (far greater than any ever caused by ordinary malnutrition or wasting disease however profound), and the character of his gastro-intestinal symptoms, I regarded the case as one of pernicious anæmia. This view was fully confirmed by the result of the necropsy, and still further by the subsequent investigation, both microscopic and chemical, which, thanks to Mr. Barker's courtesy, I was enabled to make on the material obtained from the case.

Nature of examination.—I was afforded the opportunity of being present at the necropsy, and I append the notes which I then made. I have subsequently examined microscopically the following tissues and organs—viz., blood, spleen, lymph

glands (gastric and mesenteric), liver, kidney, tongue, gums, teeth, stomach, small intestine, and colon; also chemically the liver, spleen, and kidney for iron; and, lastly, both microscopically and chemically the stomach contents. The number of sections so far microscopically examined has been close on 200.

Summary of results.—1. There were characteristic pigment changes with large excess of iron in the liver and kidney and intensely deep colour of bile denoting excessive hæmolysis. 2. The ordinary blood changes of pernicious anæmia, including the presence of nucleated red corpuscles in the blood, spleen, and glands. 3. Dental decay and necrosis with pus sacs at the roots of the teeth, collection of pus in the ethmoidal sinuses, and foul granulations around a necrotic tooth. 4. Stomach: fatty infiltration, degeneration, catarrh, and desquamation of the glandular cells; presence of cocci (oxyntic cells least affected) in the perivascular lymphatics of the submucosa at certain parts. 5. Intestine: there were no post-mortem changes. There were a number of ulcers in various stages (active, healing, and healed) above the constricted portion of the gut. At other parts there was thinning of the mucosa; the cells of the glands generally were normal; at parts there was superficial inflammatory necrosis of the mucosa due to the presence of organisms, at others replacement of glands by cicatricial tissue amidst which streptococcal organisms were numerous, and at others the presence of cocci in the perivascular lymphatics of the submucosa. 6. Colon: there were no post-mortem changes. The lymphoid elements of the mucosa were well preserved and staining was normal. (*a*) There was intense degeneration and necrosis of the glandular cells, hardly a normal cell remaining. The cells represented by granular detritus were crowded with organisms, most of them cocci, only a few bacilli; (*b*) cocci, both single and in chains, were very abundant in the deeper parts of the mucosa around the base of the glands (they were absent from the superficial mucosa) and at parts they were very numerous in the lymphatics of the submucosa. Their streptococcal nature in parts was very obvious. 7. Pus of ethmoidal sinus: "Staphylococcus pyogenes aureus and bacillus coli communis, the latter being probably a post-mortem contamination" (Dr. Eyre, Bacteriologist, Charing-cross Hospital). 8. Stomach contents: chemically there was neither free hydrochloric acid nor butyric acid. Lactic acid was present. Microscopically there were numerous organisms, including mouth bacilli. All of them were decolourised by Gram's method with the exception of a streptococcus form (streptococcus longus). The contents were deeply bile-stained, resembling closely in appearance and character the contents of the jejunum. No cultures were obtainable owing to excess of formalin. 9. The percentage of iron in the liver was 0·360; in the spleen, 0·069; and in the kidney, 0·330. To show the notable increase of iron in the liver and kidney I append for purposes of comparison the results of a similar analysis recently made in a case of gastric cancer—a case which resembled pernicious anæmia in the high degree of lemon colour and in the absence of any notable emaciation. Percentage of iron in the liver, spleen, and kideny in the gastric cancer: liver, 0·022; spleen, 0·013; and kidney 0·003.

Necropsy.—The necropsy was performed 12 or 15 hours after death. The weather was cold. There were no post-mortem changes. The body was fairly nourished. The blood was watery. The liver weighed 4 lb. 10 oz. and was fatty; the centre of the lobules was pale and the periphery was rust-coloured. A piece of liver placed in sulphide of ammonium gave marked iron reaction (blackening). The gall-bladder was filled with extremely deep golden-yellow-coloured bile. The mucosa was normal. As to the kidney, the right weighed four and a half ounces and showed a cicatrix at the lower end, the result of an old crush. The left weighed seven ounces. It was comparatively enlarged. The spleen weighed five ounces; it was red and firm, not soft. The stomach contained 120 cubic centimetres of bile-stained contents with food. There was no cadaveric softening. The mucosa showed punctiform hæmorrhages; there was considerable increase of mucus. The duodenum and intestine contents were fluid and very deeply bile-stained. The jejunum was much dilated and the walls were considerably hypertrophied above the point of narrowing (from six to seven feet below the stomach). The mucosa above the stricture showed a number of irregular ulcers, some of them cicatricial, others partially healed, and others still showing hyperæmic edges. Elsewhere the mucosa of the intestine, colon, and rectum showed nothing obviously abnormal. In the gastric and mesenteric glands there was no trace of hæmorrhages. Microscopically there was no pigment. The heart muscle was red and hyaline; there was no tabby-cat striation. The musculi papillares of the left ventricle were hypertrophied. There were a few punctiform hæmorrhages under the epicardium. The tongue was very soft on the sides; there were no ulcers. There were compound papillæ on the back part of the dorsum in front of the epiglottis slightly red and prominent. The tonsils were red. The œsophagus was normal in appearance. With regard to the teeth the incisors and canines were small, regular, and pearly white, looking quite normal. The bicuspids and molars were very bad, represented for the most part by necrotic atrophied-looking stumps, the gums around which presented a peculiar whitish sodden appearance. In the right upper jaw the first bicuspid was represented by a black stump, very small and atrophied (10 millimetres long by five millimetres wide), with a small abscess sac of about the size of a pea at its apex. The fang at the apex was dead and necrosed. The second bicuspid and first molar were represented by black fangs, the second molar had a black carious cavity in the crown, and the third molar a dark carious cavity on the outer side of the crown. In the jaw beneath these teeth was a large abscess sac 13 millimetres in diameter communicating by a fistulous sinus with the root of the second bicuspid or first molar above; bare bone was felt at the upper end of the sinus. In the left upper jaw there was a similar white sodden appearance of gums immediately around decayed roots. The wisdom tooth alone remained; the gum around it was swollen and at the back part was detached from the tooth. It was red, granulating, and inflamed; the fang of the tooth beneath was exposed and carious. On opening the left orbital cavity a large quantity of pus welled up, appearing at first as if coming from the orbital cavity; afterwards it was found to come from the ethmoidal sinuses. There were no subdural hæmorrhages in the brain. With regard to the lungs there were subpleural, punctiform hæmorrhages near the base. In the marrow of the long bones there was transformation of yellow into red marrow.

Remarks.—The case as a whole appears to me to support in a striking manner the conclusions which I put forward in the recent studies to which Mr. Barker refers. These observations denoted, I concluded, the infective nature of the condition termed pernicious anæmia, "the infection being confined to the alimentary tract, chiefly the stomach, no part of that tract from mouth to anus being safe from it." The source of infection I traced to the mouth, arising either within the mouth itself "in connexion with long-continued and neglected cario-necrotic conditions of teeth, sometimes possibly from stomatitis arising from other causes—e.g., drain poisons." The infection was "chiefly streptococcal, probably deriving its special (i.e. hæmolytic) characters from being of a 'mixed' character, the infection the more readily occurring if the stomach or intestine were already from any cause the seat of disease."

The anæmia was not due to any mere disturbances of nutrition arising from the stomatitis, glossitis, or any conditions of gastritis or enteritis which might be, and often were, found, but to the destruction of blood occasioned by the special infection. The whole group of conditions in the alimentary tract "were the local lesions of an infection, chiefly cæcal, the anæmia being the result of the destructive action of the poisons absorbed into the blood." Mr. Barker's case appears to me to present points of special interest in relation to the foregoing conclusions.

1. *Nature of the anæmia.*—That the case was one of pernicious anæmia is, I consider, conclusively established by the results of chemical analysis, showing a characteristic increase in the percentage of iron in the liver (also in the kidney). Microscopically the pigment was found within the liver cells in the outer zone of the hepatic lobule, with characteristic fatty changes in the centre of the lobule. The anæmia was thus hæmolytic in its nature.

2. *Mode of development.*—The patient suffered from more or less abdominal discomfort from the time of his accident seven years before without the development of any special degree of anæmia till the previous summer—i.e., seven months—before his death. His great pallor then became noticeable and he soon after began to suffer from shortness of breath and palpitation—i.e., five months before death. The conclusion which I form, then, is that at the time of his death he was in his first year of illness from pernicious anæmia. In his case the unhealthy conditions

of some part or other of the alimentary canal which according to my studies always precede and are necessary to successful infection, were created in the intestine above the point of stricture. As shown by the character and severity of his gastro-intestinal symptoms (pain and vomiting) these unhealthy conditions had existed from the time of his accident seven years before and it is, I consider, exceedingly probable that some of the healed ulcers found post-mortem above the seat of stricture were remains of lesions resulting therefrom. With comparative suddenness there was superadded to his general abdominal discomfort the feature of intense pallor with all the symptoms—e.g., palpitation, breathlessness, diarrhœa, and vomiting, varying febrile attacks (see Mr. Barker's account of the illness in September, 1899)—which are so characteristic of pernicious anæmia, and from that time forward what troubled him most—what he sought admission into hospital for—was his extreme weakness and anæmia complicated by periodical attacks of pain and vomiting connected with his intestinal condition. This relation of events—a history of antecedent gastric or intestinal trouble extending usually over many years, more or less suddenly followed by a rapidly developing anæmia out of all proportion to the actual extent or severity of lesion existing in the stomach or intestine—I find in my experience of the disease to be the typical mode of development of pernicious anæmia. And this more or less suddenness of development, with the extraordinarily high degree of anæmia (exceeding anything ever met with even in the severest forms of wasting anæmia) are the clinical features which I have come to regard as denoting the supervention of a new factor—viz., successful infection of some part or other of the alimentary canal.

3. *Evidences of infection.*—In the present case the evidences of infection of the mucosa, to a slight extent of the stomach and to a still greater extent of the intestine and colon were undoubted—notably (1) the small areas of the superficial ulceration and necrosis with inflammatory changes in certain parts of the mucosa of the small intestine, with presence of organisms confined to these areas and to the lymphatics of the submucosa; and (2) the very striking degeneration and necrosis of the cells of the tubules in the colon associated with presence of organisms also confined to the tubules and to the subjacent lymphatics of the mucosa and submucosa.

That the invasion of the mucosa was no mere post-mortem phenomenon is, I consider, clear from the following: (*a*) In the case of the stomach only in one part microscoped was there slight superficial post-mortem change in the mucosa, and at this point no organisms at all were found. On the other hand, the organisms were found in the lymphatics of the mucosa at prolated parts where no post-mortem changes were shown. (*b*) In the case of the small intestine the cells of the tubules generally showed no change and no organisms were present in them. On the other hand, where the organisms were present they were surrounded by evidences of inflammatory reaction—viz., nuclear fragmentation and necrosis. (*c*) In the case of the colon the organisms were confined to the degenerated and necrosed cells of the glands and to the lymphatics underlying them. They were not present amidst the lymphoid tissue of the general mucosa.

4. *Nature of infection.*—As regards the nature of the organisms present and their relative importance any decision from their microscopical characters alone is naturally impossible. The contents of stomach and intestine were much alike in character and both were bile-stained, so that it is certain that the ordinary intestinal organisms (bacillus coli) were present in the stomach no less than in the intestine. In the mucosa, and especially within the lymphatics, however, the organisms present were not bacilli but cocci, and especially streptococci (Zeiss, $\frac{1}{12}$ oil immersion), and a streptococcus was also present in the stomach contents. As this organism is undoubtedly pathogenic I am disposed to attach to it the chief importance. The infection of the mucosa was chiefly coccal and streptococcal.

5. *Source of infection.*—On this point—the one to which my recent observations more especially referred—no information was forthcoming from the history of the patient. He was too ill to be questioned. He had been well fed and had lived among healthy surroundings. With regard to any dental or oral trouble his wife informed me in reply to inquiry that he had not suffered in that respect. The examination, cursory in character, which I made at the time I saw him a few hours before his death, when he was already sinking, seemed to bear out this statement, for the front teeth which he showed me on opening his mouth seemed exceptionally good and healthy, so much so that I mentally registered the case as one affording no support to the recent conclusions regarding the prevalence of decayed teeth and their importance as a possible source of pyogenic infection in pernicious anæmia.

As it turns out, I cannot but regard the case as a most remarkable one in this relation, for I found at the necropsy that the front teeth were the only good ones. The remainder were for the most part represented by black roots lying in sodden white gums. At the roots of these, in one side of the jaw alone, were two abscess sacs, the larger being of the size of a small hazel nut. Moreover, on opening the left orbital cavity pus welled out in quantity from the ethmoidal sinuses. Of this condition of mouth or nose there was not, be it noted, the slightest suspicion during life and not the slightest symptom. This was one of the points to which I drew special attention in the observations recently recorded. I considered it "all-important in all cases of commencing anæmia that special attention should be directed to the condition of the teeth ..... by removal not only of old stumps, but also of all black teeth, and of teeth showing commencing cario-necrosis ..... these precautionary measures being necessary, irrespective of any statements made by the patient as to the degree of discomfort his teeth are causing. For in no single case observed, however bad I found the teeth to be, was my attention drawn to the teeth by the patient or any complaint made of them by him. There is a stage in pyogenic conditions as in other forms of infection when local reaction—e.g., pain or inflammation—is absent or insignificant at the very time when the general septic effects are most marked."

The case just recorded bears out—if possible even more fully than I had anticipated—the correctness of these statements. Without occasioning the slightest local discomfort there existed a profoundly septic condition both of jaw and ethmoidal sinuses. How long these decayed teeth had existed I have no means of knowing. But I note with interest the statement in his history that "he had always suffered from 'heartburn' worse since the accident," a symptom denoting existence of chronic gastric catarrh. The close relationship between dental cario-necrosis and gastric catarrh is the point which I have recently had occasion to elucidate. The two conditions are precisely those most favourable to infection of the mucosa of the stomach, and ultimately, if the conditions be favourable, as in the present case, to infection of the intestine lower down. For on the one hand there is diminished resistance on the part of the stomach from the diminished acidity of gastric secretion consequent on the catarrh; while on the other hand there is increase of dose from continuous swallowing of pus organisms from the necrotic teeth. In the present case both these conditions were met. The patient had infection of the mouth, and the gastric contents contained no free hydrochloric acid.

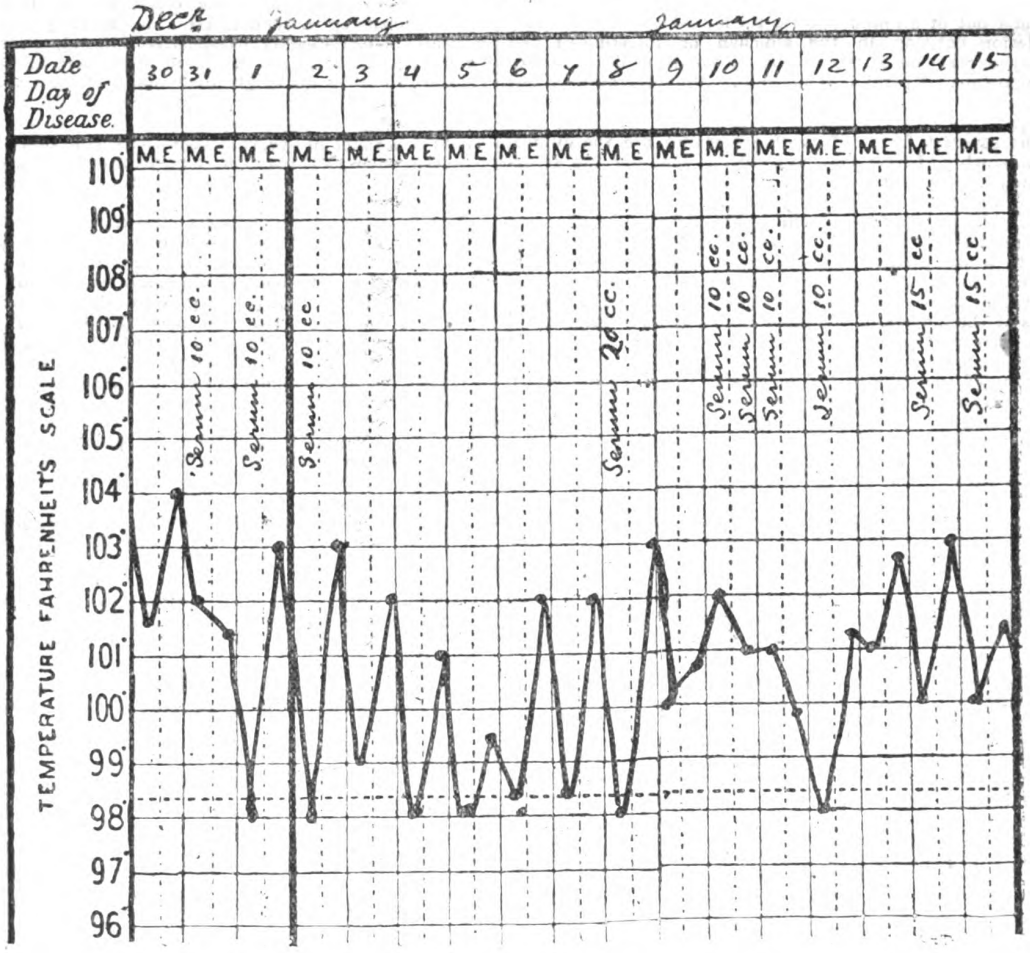
SUMMARY.

The relations of events in the case I would then summarise as follows:—

1. A man, temperate, well fed, and living in healthy surroundings.
2. Bad teeth causing alternately alveolar and ethmoidal suppuration without at any time occasioning local discomfort.
3. Always suffered from "heartburn" (denoting chronic gastric catarrh with diminished acidity of gastric juice).
4. Accident causing stricture of jejunum.
5. More or less severe abdominal and gastric symptoms lasting six years.
6. More or less rapid supervention of the features of pernicious anæmia nine months before death.
7. Post mortem (1) dental decay with local complications—e.g., alveolar and ethmoidal suppuration; and (2) definite infection (coccal and streptococcal) of the mucosa of the intestine and colon, with definite catarrhal, inflammatory, and necrotic changes—to a less extent of the stomach.

THE LATE MR. J. FLINT SOUTH, F.R.C.S.—Mrs. C. Stuart Andreae and Miss Mary F. South have forwarded to the treasurer of St. Thomas's Hospital a donation of £1000 to endow, in perpetuity, the "South Bed, as a memorial of the late Mr. J. F. South, who was for some years surgeon to that institution."

A CASE OF ULCERATIVE ENDOCARDITIS, WITH RECOVERY UNDER THE USE OF ANTI-STREPTOCOCCIC SERUM.



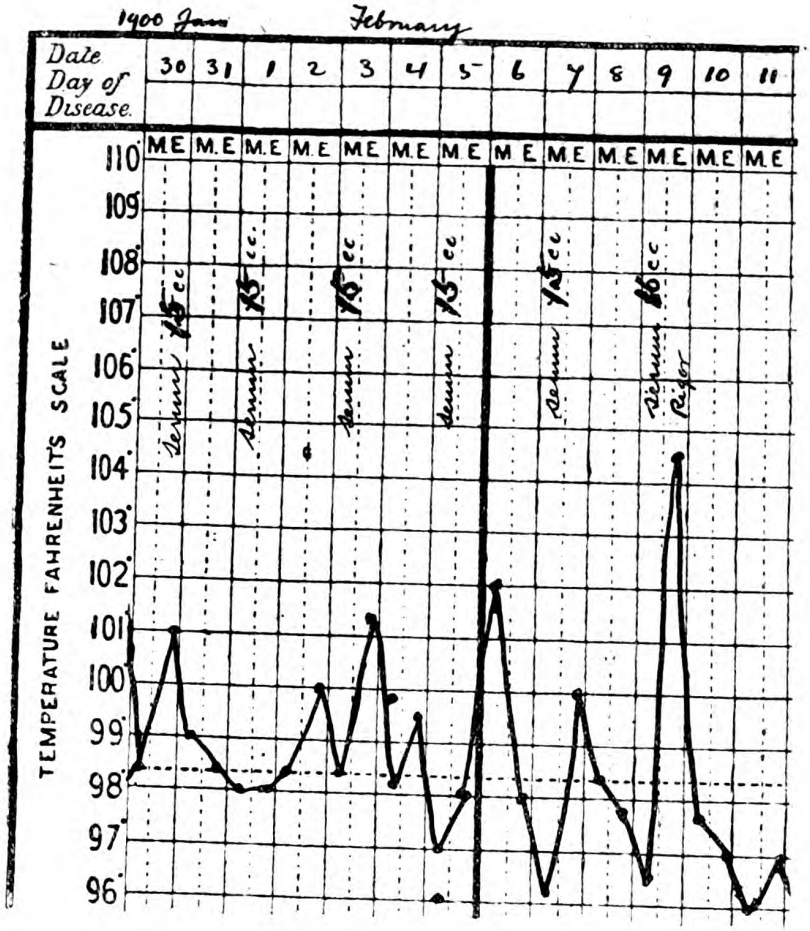
BY J. MICHELL CLARKE, M.A., M.D. CANTAB., F.R.C.P. LOND.,

PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, BRISTOL; PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

As the employment of anti-streptococcic serum in ulcerative endocarditis is still on its trial I have thought it worth while to report the following case in which it was successfully used. The patient was a single woman, 22 years of age. She had enjoyed good health until the age of 18 years, when she had what was called an attack of muscular rheumatism which laid her up in bed for six weeks. She then improved and was able to get about for two weeks, but developed pleurisy with effusion on the left side. She recovered from this and subsequently remained fairly well, but was delicate and liable to suffer from cough and from shortness of breath on exertion. She came to me on Nov. 14th, 1899, complaining of weakness, shortness of breath, pain in the præcordial region, and slight swelling of the ankles. She also said that during the previous fortnight she had felt hot in bed at night and had had two attacks of slight shivering accompanied by blueness of the lips and pallor of the face. She was tall, thin, and anæmic. The temperature was normal and the pulse was 110 and weak. The lower part of the left side of the chest was slightly contracted as a result of the attack of pleurisy. The heart's apex gave a forcible impulse in the nipple line in the left fifth space; dulness extended transversely from the nipple line to the right border of the sternum and upwards into the second left intercostal space; and a loud systolic murmur was present at the apex and right base and was audible at the angle of the left scapula. The liver was slightly enlarged. The urine contained no albumin.

The patient was kept in bed; the temperature rose two or three times in the evening to 100° or 101° F., and she appeared to be doing well, when on Dec. 6th she had a rigor and the temperature rose to 103°. On the 7th a small patch of broncho-pneumonia developed just below the angle of the right scapula and she expectorated a little blood-stained sputum. In the light of the subsequent progress of the illness this attack was probably due to an infarct into the lung. The temperature remained at from 102° to 103° for three or four days and then fell to normal and remained so for about a week when it began to rise again in an irregular fashion. The subsequent course of the temperature was as follows from the 19th to the 28th, 1899, inclusive:—

FIG. 1.



Date.	Morning.	Evening.
Dec. 19th ...	— ...	102·0° F.
,, 20th ...	98·0° F. ...	102·6°
,, 21st ...	97·4° ...	102·0°
,, 22nd ...	96·8° ...	103·0°
,, 23rd ...	97·6° ...	102·6°
,, 24th ...	97·0° F. ...	104·0° F.
,, 25th ...	98·0° ...	103·0°
,, 26th ...	99·0° ...	101·6°
,, 27th ...	97·0° ...	101·4°
,, 28th ...	98·0° ...	100·0°

From the 29th to Jan. 15th, 1900, inclusive, the course of the temperature is shown in the accompanying chart (Fig. 1).

On Dec. 23rd the patient felt weak and she was anæmic; there was a peculiar deep-red, at times almost livid, flush on the cheeks. No spots were seen, no hæmorrhages occurred, she took food well, and there was no vomiting or headache. Except for a few râles at the bases the lungs were normal. The heart's apex was forcible and slapping in the nipple line; there were dulness, some bulging, and forcible pulsation in the second and third intercostal spaces close to the left border of the sternum. In addition to a systolic murmur at the apex a loud systolic murmur had appeared over the pulmonary area and a faint diastolic murmur at the right base. The pulse was 120, weak, and collapsing in character; the respirations were 26 to the minute. The edge of the liver could be felt and the spleen was not enlarged. There was no albuminuria. On Dec. 28th and again on the 31st a hypodermic syringeful of blood was withdrawn from the median basilic vein. Dr. D. S. Davies kindly undertook the bacteriological examination of the specimens, which proved to be free from micro-organisms. On the 31st treatment with anti-streptococcic serum was begun. Previously to this the patient had been treated with full doses of sodium salicylate, salicin, and salol, but without any effect on the irregular rises of temperature. On Jan. 6th, 1900, the systolic and diastolic murmurs at the base resembled a friction sound; the latter, however, was conducted down the left sternal border and was audible over the ensiform cartilage. Dr. Shingleton Smith saw her with me about this time and he agreed in the diagnosis of ulcerative endocarditis. On Jan. 12th the patient seemed weak; the pulse was 96, weak, and collapsing; the respirations were 24. 40 ounces of urine were passed, of specific gravity 1022; it was acid and was loaded with urates, but was free from albumin. The appetite was poor; there were no spots and there was no headache or sickness; the cheeks were still deeply flushed. There was no cyanosis; the veins in the neck were rather full. The heart's apex was now half an inch outside the nipple line; dulness extended upwards to the second rib and one inch beyond the right border of the sternum. The systolic murmur was now loudest in the second left intercostal space and less distinct at the apex and the aortic area. The to-and-fro systolic and diastolic murmur was still audible over the sternum; this murmur varied much in intensity from day to day, sometimes being loud and at other times almost inaudible. A systolic murmur was now generally audible to the right of the sternum in the fourth and fifth spaces. All the murmurs showed much variation on different days. The course of the temperature from Jan. 16th to Jan. 29th inclusive was as follows:—

FIG. 2.

Date.	Morning.	Evening.	Date.	Morning.	Even
Jan. 16th	99·8° F.	103·0° F.	Jan. 23rd	98·4° F.	99·8° F.
,, 17th	97·0°	100·8°	,, 24th	98·0°	100·2°
,, 18th	98·4°	101·0°	,, 25th	98·0°	101·0°
,, 19th	98·4°	100·2°	,, 26th	98·0°	101·0°
,, 20th	98·4°	101·4°	,, 27th	98·0°	101·6°
,, 21st	98·0°	102·0°	,, 28th	97·0°	101·0°
,, 22nd	97·8°	101·4°	,, 29th	99·6°	101·4

On Jan. 21st the heart sounds at the apex had an approach to a galloping rhythm with a double second sound.

From about Jan. 20th the patient began to improve; she gained strength and was cheerful and anxious to get up; her colour improved and the flush left her cheeks, her appetite returned, and her temperature took a lower level. The pulse varied from 84 to 96 and the respiration rate was 22. From Jan. 28th she was carefully lifted on to a couch for some hours each day. From Jan. 30th to Feb. 11th inclusive the course of the temperature is shown in the accompanying chart (Fig. 2). On Feb. 3rd the chief murmur was a soft to-and-fro systolic and diastolic murmur at the base, loudest over the pulmonary area. No thrill was ever felt over any part of the area of cardiac dulness. The lungs were normal. She improved all through February, the temperature remaining subnormal after Feb. 9th. By Feb. 21st the cardiac dulness was much diminished in size; it still extended to half an inch outside the nipple line to the left, but above it stopped at the upper border of the third costal cartilage, and to the right it did not go beyond the right border of the sternum. The diastolic murmur had disappeared and there was only a long churning or grinding systolic murmur, loudest at the left base.

After this time it is sufficient to say that the patient steadily improved. On account of anæmia she was now given 10 minims of tincture of perchloride of iron three times a day. On March 4th she was allowed to walk about in her room and on the 11th to walk downstairs. On the 18th she was able to walk upstairs and downstairs without difficulty or shortness of breath, and after being up the greater part of the day there was no œdema of the ankles at night. The temperature was generally a little subnormal, the pulse-rate was 84 and regular, the respiration rate was 20, and the lungs were normal. The heart's apex had returned to the nipple line, the area of dulness had diminished, and the only murmur present was a quiet systolic murmur loudest over the aortic orifice, but also plainly audible at the apex and angle of the left scapula. The aortic second sound was accentuated.

The catamenia, which had been absent since October, returned at this time. The patient remained well for another three weeks and then went to the seaside. The anti-streptococcic serum used was obtained from the Jenner Institute. Mr. George Dean, bacteriologist in charge of the antitoxin department, kindly wrote to say that this serum "was derived from four horses. I used several races of streptococci in immunising these horses; the serum therefore was a polyvalent one. These streptococci were derived from cases of (1) acute abscess; (2) ulcerative endocarditis; and (3) puerperal septicæmia. Two of the races had been exalted to a very high virulence by passage through rabbits." 232 cubic centimetres of the serum were used. 10 cubic centimetres were given at each injection at first; the first injections were followed by a great deal of pain and acute tenderness at the site of inoculation, which became red, swollen, and infiltrated, this swelling and tenderness lasting for a period of from 36 to 48 hours. To secure sleep 15 minims of liquor morphinæ were sometimes given on the night following the injection. After the first five or six injections the patient was troubled with general urticaria which came on three or four hours after each injection. This urticaria was very pronounced and caused intense irritation; it invariably disappeared in the most remarkable way about half an hour after the administration of 15 grains of calcium chloride. The same serum was used throughout.

It will be seen from the chart (Fig. 1) that after the first three injections the temperature fell steadily (by lysis) for four days. As it began to rise again I thought it advisable to give a larger dose and I injected 20 cubic centimetres on Jan. 8th. For some hours after this the patient seemed very poorly, faint, and weak, with a feeble pulse. I did not think it advisable to give so large a dose at one time again, and after giving a dose of 10 cubic centimetres twice a day for two days I administered a dose of 15 cubic centimetres, which seemed to be the proper one in her case. From the 15th to the 28th the improvement in her general condition was so marked that I stopped the injection of serum. So far the injections had always given her much local pain and discomfort, as above stated, and this upset her and kept her back, so that partly on this account I was glad to give her an interval of rest. But on the 28th, as the temperature, though lower in range, was still oscillating in character and above normal, I recommenced the injections. From this time they gave rise to no local pain, urticaria, or red blush at the site of injection, and very slight swelling, but now to constitutional symptoms, consisting of headache and a feeling of malaise for some hours. The same serum was used throughout. On Feb. 9th, at 10 P.M., on the occasion of the sixth injection of the second series, a few minutes after injecting 16 cubic centimetres the patient said that she felt very ill; the respiration became rapid, there was well-marked cyanosis, the pulse was 120 and very weak, and she seemed very ill. She took a teaspoonful of sal volatile and in a little time she was better. The cyanosis lasted about 10 minutes. About noon she had a slight rigor and the temperature rose to 104·6°. She felt ill all day but improved towards evening, the temperature falling to 101° by 9.30 P.M. It is remarkable that after this injection her temperature never rose again but remained for some time subnormal, and her pulse varied from 72 to 80. This seemed the turning-point of her illness, which thus appeared to end by a sort of crisis. Interesting points are the pronounced local effects of the first injections, their disappearance with later ones, and the occurence of constitutional (general) effects. I may add that no changes were found in the urine after the injections and that the punctures all remained aseptic.

I saw the patient on May 3rd after she had spent a month at the seaside and she looked fat and rosy. At first there had been some œdema of the ankles, but this had now passed off and her only trouble was slight shortness of breath on exertion. The heart's apex was in the fifth space in the nipple line, and there was a loud blowing systolic murmur accompanying the first sound, loudest in the aortic area, but audible over the whole of the præcordium and in the back.

Since recovery from ulcerative endocarditis is very rare it may be objected that this was not a case of that disease, but should rather be considered one of rheumatism with pericarditis. But in favour of the former diagnosis are (1) the presence of a chronic valvular lesion on which an infective process is apt to graft itself; (2) the fact that the illness did not yield to the several salicylic compounds which were tried in full doses without effect; (3) the occurrence of a pulmonary infarct; and (4) the steady progress of the patient from bad to worse until treatment by serum was begun, which treatment again would have had no influence on acute rheumatism. I may also mention as possibly of importance in etiology that the patient's house adjoined a large graveyard, now, however, only occasionally opened, that there were several large trees in front of it, and that the first symptoms began in the autumn. These facts are interesting in connexion with Sir T. Lauder Brunton's suggestion that endocarditis is more liable to come on at the time when the leaf falls.[1] I think it also of importance that the serum treatment was begun early.

Clifton, Bristol.

THE VARIETIES OF ACUTE PNEUMONIA.[2]

BY HENRY HANDFORD, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN TO THE GENERAL HOSPITAL, NOTTINGHAM.

THIS subject is far too large for me to deal with exhaustively. I will confine myself to two points—varieties in symptoms and physical signs and varieties in causation. I am speaking only of lobar pneumonia and not at all of lobular or broncho-pneumonia. In an ordinary typical case no difficulty in diagnosis can arise, but exceptional cases may puzzle the most experienced. A physician so expert in physical diagnosis as Dr. Samuel Gee[3] writes: "A physician well read in the book of nature knows that he cannot *always* distinguish between pleurisy and pneumonia. ..... It much more often happens that a small pleural effusion is mistaken for pneumonia. The physical signs of the two diseases may be the same and even puncture is not always decisive."

A rare but somewhat puzzling symptom is low temperature. The following was a serious case of pneumonia where the temperature never exceeded 100·5° F. It occurred in the person of a stout, active man, aged about 56 years, vigorous both in mind and body. One morning, feeling

[3] Allbutt's System of Medicine, vol. v., p. 369.

upset, he remained in bed and in the evening had a temperature of 100·5°, cough, and signs of bronchitis. On the following morning—the second of his illness—his temperature was 99·8°, his respiration was 32, and his pulse was 104. He had a frequent irritable cough, which was increased by any movement; his tongue was coated with a yellow fur and there was general prostration. He was coughing up abundant, sticky, fibrinous sputa which adhered to the vessel and did not move when the vessel was inverted. The sputa were abundantly stained with bright blood. On examination impaired percussion resonance was discovered in the left axilla and at the left base, where also there was distinct tubular breathing and bronchophony. Pleuritic friction was audible over a limited area at the lower and back part of the axilla. He was given three grains of calomel and a mixture containing carbonate of ammonia and ipecacuanha. Notwithstanding the moderate temperature he was very ill and prostrate and seemed more likely to die than recover. On the third day his temperature in the morning was 99·8°, his pulse was 104, and his respiration was 28; and in the evening his temperature was 100·1°, his pulse was 108, and his respiration was 30. He was still spitting blood but was decidedly improved. On the fourth day his temperature in the morning was 97°, his respiration was 24, and his pulse was 96. His midday temperature was 98·4°. In the evening his temperature was 97·6°, his respiration was 24, and his pulse was 83. He was improved. The sputum was still fibrinous and it adhered to the vessel but it was less blood-stained. There was pleuritic pain on coughing. Dulness and tubular breathing were still quite distinct. On the fifth day his morning temperature was 97·8°, his respiration was 24, and his pulse was 80. There was now no pain on coughing. For the first time he could lie on the left side. The sputa were barely blood-stained and were becoming frothy. Tubular breathing was still distinctly audible at the left base but was quite gone from the axilla. On the seventh day his morning temperature was 99·2° and his pulse was 100. His evening temperature was 100°. There were occasional râles at the back and a rub in the axilla. He was over-fatigued by having several business interviews in bed. On the ninth day his temperature was 99·0° and his pulse was 88. The pleuritic rub and tubular breathing were quite gone. On the tenth day and afterwards his temperature remained normal and he was convalescent, but it was a fortnight before he regained strength sufficiently to walk out of doors and to go away from home.

In this case the patient's age, stoutness, and habits all tended to make an attack of pneumonia unusually dangerous; but by the fourth day all immediate danger had subsided, although the physical signs remained typical. From the amount of sputa and the area of dulness the extent of lung consolidation could not have been very small and yet there was never high fever. Wilson Fox [4] says: "A few rare and exceptional cases of pneumonia existing without fever have been recorded, but it must be remembered that the pyrexia of pneumonia may last in some cases for only a few hours while the consolidation persists after the fever has disappeared. The occasional apyrexial character of pneumonia is supported by the high authority of Wunderlich. Lebert observed a case where the temperature only reached 100° F. on the sixth day." As a marked contrast to this may be mentioned cases recorded by first-rate observers where the symptoms, both general and special, are well-marked and undoubted, but physical signs are scanty or absent. Some of these it has been proposed to explain by suggesting that the area of lung affected is near the root and does not reach the surface. In other cases it has been suggested that the general symptoms of pneumonia are caused by the products (toxins) of the pneumococcus which may be growing in other organs or places than the lung. As has been recently written: [5] "Most physicians have seen cases of acute pleurisy the clinical course of which has been indistinguishable from that of a pneumonia, but in which post mortem the lung is not found hepatised. In these it is not surprising to learn that the pneumococcus has been found in the pleural lymph by Dr. Washbourn."

This leads me to the second part of my subject—namely, varieties in causation. I hope it will be agreed that it is not sufficient nowadays merely to diagnose pneumonia, but that an attempt should be made to ascertain the cause. Much, both in prognosis and in treatment, may depend upon the cause. Many years ago Skoda,[6] in Vienna, taught that pneumonia was a specific *general* disease, and, pointing to a patient with the general symptoms of pneumonia but with no physical signs in his lungs, argued that this proved that there was a general infection of the blood before the local changes occurred. Some years ago, too, Wilson Fox in his monograph on Pneumonia came to the conclusion that the causes of acute pneumonia were not one but varied.

Of recent years more precision has been given to the question by bacteriology, but much remains to be done, and the subject is by no means worked out. Weichselbaum,[7] in Vienna, in 129 cases of pneumonia discovered the pneumococcus (Fränkel's diplococcus) in 94, Friedländer's bacillus in nine, streptococcus pyogenes in 21, and staphylococcus pyogenes aureus in five. There is also the rod-shaped microbe which was found by Dr. Klein in the epidemic pneumonia of Middlesbrough. Thus the theory of a variety in causation is supported by the variety of micro-organisms found. Moreover, the pneumococcus, which is the micro-organism most commonly found in pneumonia, is sometimes found in lobular pneumonia, sometimes in pleurisy without pneumonia, sometimes in endocarditis and in epidemic cerebro-spinal meningitis, and sometimes in healthy saliva.

It is hardly necessary to point out that the symptoms of pneumonia are not entirely due to the local inflammation of the lung tissue, but in great part to the specific nature of the poison. Not infrequently the symptoms precede the physical signs by several days; the temperature and even the number of respirations fall when the crisis comes, long before the solidified lung has cleared up; and the violence of the fever is not in proportion to the extent of the local lesions. There is much reason to think that the wide variations in symptoms, course, and fatality may coincide with differences in the micro-organisms which predominate in the diseased lung. No one could expect a plague pneumonia, a typhoid pneumonia, and an influenza pneumonia to run the same course.

One of the best examples of specific pneumonia is influenza pneumonia. This usually follows an attack of evident influenza, but in some cases it is the only manifestation of the disease. Probably the latter group accounts for most of the instances of *infection in pneumonia*.

Although the question of infection has been occasionally mooted for many years past its exact position is hardly yet accurately defined. In an experience of over 20 years I have never seen a case of pneumonia in the general hospital give rise to a second case in the same ward or building, neither have I ever known a nurse or medical man to be infected from a patient. We may therefore take it that under hospital conditions, with good sanitation and free ventilation, pneumonia does not ordinarily spread to patients in adjoining beds or to attendants. But in spite of this experience and of the long-established tradition that pneumonia is not an infectious disease cases do occasionally arise which clearly show that under less favourable circumstances pneumonia does spread by direct infection. Wilson Fox [8] quotes Hardwick to the effect that "(1) a priest attacked by pneumonia communicated it to a relation who visited him, and who again communicated it to another relative; and (2) an old man at the point of death from pneumonia sent for his relatives, each of whom was subsequently attacked." It may very well be that some kinds of pneumonia are more infectious than others, especially the pneumonia of influenza. It is highly probable that the six cases which I am about to describe were of this nature. Although influenza was not prevalent at the time in that neighbourhood there were no other signs of influenza and there were no cases of simple influenza or other illness in the house. The first two cases I saw in consultation with Dr. J. J Bingham of Alfreton, the other four were less severe and were kindly communicated to me by Dr. Bingham. The cases occurred in January and February, 1899, in the members of one well-to-do family and in one house.

On Jan. 7th, 1899, a little girl, aged 6 years, was taken ill with symptoms of pneumonia and very soon there were signs

of consolidation of the right base with a temperature of 104° F. Four days later the left base became affected. On Jan. 16th, the ninth day of illness, I was asked to see her and found her with a frequent, distressing cough. Her temperature was 101° F., her respiration was 64 per minute, and her pulse-rate was 140. There were Skodaic resonance at the left apex, dulness to percussion in the axilla and lower three-quarters of the left back, increased vocal resonance with loud tubular breathing, and râles over the dull areas. The heart was not displaced. The right base had nearly cleared up. She was nursed chiefly by her mother and spent many hours lying in her mother's arms. I saw her again nine days later—i.e., the eighteenth day—when she was approaching convalescence with a nearly normal temperature and greatly improved general condition, but the dulness and whiffing tubular breathing still remained. She ultimately got quite well.

On Jan. 20th, four days after my first visit to the preceding patient, the mother had a severe rigor and a temperature of 104° F. on the following morning. At my second visit on Jan. 25th her temperature was 102° F., her respiration was 64, her pulse was 160, and she was constantly delirious. There was pneumonic consolidation of the right base and of almost the whole of the left lung. She died early on the following morning, the sixth day of her illness.

A week later, Feb. 2nd, the elder girl, aged eight years, was taken ill with pneumonia. Four days later, on Feb. 6th, a brother, aged 12 years, was seized; and on the next day another brother aged 14 years. Again, one day later, on Feb. 8th, the father was affected. With the exception of the mother, who died, all the patients were ill in bed at the same time suffering from pneumonia and they recovered.

In April, 1900, I was asked to see in consultation with Dr. Buckley of this city a child, aged one year and three months, who was suffering from well-marked lobar pneumonia of both bases. Her temperature was 103·6°, her pulse was 150, and her respiration was 60. The child died. I ascertained that the child's aunt, living in the same house, had only just recovered from a very severe attack of pneumonia in which the temperature had reached 104·6° and in which resolution was by crisis.

There is no doubt that pneumonia does not occur uniformly distributed throughout the year, but is frequently met with in groups of cases not necessarily directly connected, or in small local epidemics. Most of the numerous recorded epidemics have occurred in prisons, workhouses, or ships, and have been associated with overcrowding and bad sanitation. That has not, however, always been the case. I have a letter from Dr. Cardno Still of Shepshed, dated June 15th, 1894, in which he writes: "From a scientific point of view I thought you might be interested to know that we have an epidemic of pneumonia. It has been going on since the end of January. There have been 28 cases and eight deaths. It seems to be almost entirely lobar. The epidemic is confined to the parish—not the village alone—and the surrounding villages are exempt. We have nothing in common here except the atmosphere, for the water-supply is from wells, the sewerage is limited, and the milk is from 20 or more sources. Those following indoor and outdoor occupations are alike attacked. It affects both sexes, but chiefly males, and with few exceptions all are adults." In a subsequent letter he writes: "In 1896, between Dec. 11th and 31st, we had 11 cases and one death."

I had neither the time nor the opportunity to make any local investigation and I believe the cause was never ascertained, but it reminds one somewhat of the Middlesbrough epidemic. That was an example of the next group I come to—namely, *food pneumonias*—that is to say, pneumonia produced by eating poisonous food. "The Middlesbrough epidemic of pleuro-pneumonia was clearly traced by the late Dr. Ballard to the use of American bacon which was made by soaking in water and then only slightly drying salted pork. This bacon was proved to be poisonous to animals fed with it and lung lesions were produced. ..... The Middlesbrough epidemic of food poisoning is to be looked upon as the result of the ingestion of a pneumonia-producing micro-organism."[9] In this instance a pulmonary lesion was caused by infection through the alimentary canal, lacteals, mesenteric glands, thoracic duct, subclavian vein, right side of the heart, and pulmonary arteries, just as no doubt many cases of pulmonary tuberculosis arise through the alimentary canal from the ingestion of the tubercle bacillus in milk.

Another form of pneumonia of which we have seen nothing in modern times in this country is *plague pneumonia*, but the experiences of Vienna as well as of India show that in this exceptional form of plague the resemblance to ordinary (croupous) pneumonia is so close that the first cases are seldom diagnosed. Bubonic plague, as is known, specially implicates the lymphatic system and glands, and it is conceivable that the early infection of the lung is due to the failure of the glands to check the course of the poison on its way to the veins and right side of the heart.

The last form of pneumonia of which I propose to speak is *typhoid pneumonia*. I do not allude to the pulmonary catarrh, or broncho-pneumonia, which is found in some degree in a large majority of the severe cases of enteric fever. I refer to a very much more restricted but sharply defined class of cases, of which I have seen several. They commence with an attack of acute lobar pneumonia displaying the usual symptoms and physical signs, and it is only by the prolonged duration and after-course of the illness that enteric fever is suspected. In three cases at present in my mind the pneumonia attack was typical and was the commencement of the illness. In one the presence of enteric fever was proved by finding well-marked intestinal lesions post mortem. In a second the presence of spots, intestinal distension, and copious intestinal hæmorrhages established the diagnosis beyond doubt. This patient recovered. The third occurred in a lad, aged about 15 years, who was admitted into the Nottingham General Hospital with a sharp attack of acute pneumonia. By the seventh or eighth day the temperature fell to about 100° F., but after a few days it began to rise again. He then went through a well-marked attack of enteric fever and recovered. In this case, although the temperature did not reach normal between the two illnesses, there was more of an interval than in the other two. Dietl thought that "the poison of typhoid might attack the lungs instead of the intestines, and Sturges has also expressed the opinion that pneumonia may be only another localisation of typhoid." Wilson Fox[10] writes: "There are, it is true, a certain number of cases where pneumonia commences early in typhoid fever and where it is liable to be mistaken for the primary disease. Such cases are very rare; they do not show critical symptoms and with the further progress of the case the character of the typhoid fever become marked." Bonnemaison relates how in one house a man and his wife died from malignant pneumonia; soon after a son and daughter suffered from typhoid fever.

I do not know whether the typhoid bacillus was present in the lung in the cases which I have mentioned. They occurred several years ago when the micro-organisms associated with pneumonia were less well known. I was inclined at the time to consider them as instances of double infection, the pneumonia organism developing more quickly in the lung than the enteric organism in the intestine, but I have been led to think that there may have been only one poison and one channel of infection. We have seen that the infection of pneumonia may enter the lung through the intestine (e.g., Middlesbrough food epidemic); and I am equally convinced that the poison of enteric fever may enter through the air passages. I am aware that this is denied, but until comparatively recently it had been erroneously taught for one or two generations that there was an absence of direct infection in typhoid fever.

One further point and I have done, and that is the influence of bad sanitation in producing pneumonia. To quote Wilson Fox[11] again: "Many isolated cases of pneumonia orginate in insanitary conditions of house drainage." Out of 1065 cases of pneumonia from the Collective Investigation Record in 47·5 per cent. the sanitary state of the house was bad, doubtful, or indifferent.

In conclusion, I think I have now given some reason for the opinion with which I commenced, that the causes of pneumonia are various, and have offered some explanation, however inadequate, of the fact that several micro-organisms have been found associated with the same disease.

Nottingham.

RODENT CANCER OF THE CORNEA; OPERATION; RECOVERY WITH RETENTION OF GOOD SIGHT.

BY SYDNEY STEPHENSON, M.B. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, ETC.

RODENT cancer of the cornea is undoubtedly one of the rarest affections of the eye. Indeed, so far as I know, not a single case has yet been reported in periodical English literature. Since the malady was described by Mooren in 1867[1] several excellent papers upon the subject have been published abroad. One of the latest, by Schmidt-Rimpler of Göttingen, is especially valuable. It contains the first account of the pathological examination of an eye affected with rodent ulcer. It may be found by those interested in the *Bericht der Ophthalmologischen Gesellschaft*, Heidelberg, 1898, p. 114. The rarity of rodent corneal cancer renders it almost unnecessary to offer any apology for recording a case which I was enabled to follow rather closely and to operate upon with success.

The patient, a female, 60 years of age, was seen by me on May 17th, 1897, in consultation with Mr. Frederick E. Fenton of Ealing. It appeared from the history of the case that the left cornea had become ulcerated in the previous March, but under Mr. Fenton's treatment that soon subsided, only to be followed by redness of the right eye. The patient, a hale and hearty person of determined character, had herself never suffered from definite gout or rheumatism, although her maternal grandfather had died at an advanced age from the former affection. The patient regarded herself as extremely subject to "colds." Upon examination the right eye showed several of the curious violet elevations or nodules characteristic of scleritis. Two months later (July 16th) the condition was as follows: Right eye.—A large, somewhat elevated patch of episcleritis lay on the outer side of the eyeball, its central parts being rusty and soft-looking and its peripheral parts pinkish-red. The nodule was not tender. There was a little photophobia, but tension was normal and there was no iritis. The lower outer quadrant of the cornea was rather hazy and a few vessels ran into it from the neighbouring sclero-corneal margin. There had been some pain, chiefly nocturnal, in the right temple. Left eye.—A corneal haze was present in the lower inner quadrant of the cornea. A change to the seaside was recommended and the patient was not seen again until Sept. 16th. On that date the outer side of the right eyeball showed a large patch the centre of which was slate-coloured and the periphery dull-red. Its central, dark-coloured area looked almost pulpy in consistence. Neither tenderness nor pain existed. The general condition was good.

The patient was not seen again until May 10th, 1898, when Mr. Fenton asked me again to examine her. The episcleritis from which she suffered was said to have made slow though satisfactory progress until April 24th when the cornea was slightly injured whilst taking off her glasses. The eye since then had watered, been sensitive to light, and had felt generally uncomfortable. Right eye. — The episcleritis had left behind it a slightly depressed, lenticular patch of slaty hue. An oval ulcer of singular appearance now involved a limited portion of the outer side of the cornea below the horizontal meridian. Towards the sclera it was bounded by a vascular area and enlarged conjunctival vessels, and its cavity appeared to be filled with some kind of gelatinous material. The palpebral conjunctiva was slightly reddened. The iris was active and not discoloured. There was no lacrymal mischief. Tension was normal. Vision, $\frac{6}{18}$. Left eye.—There was a haze over the cornea, as mentioned previously. Tension was normal. Vision, $\frac{6}{12}$. The treatment advised included (*a*) the application of iodoform to the ulcer; (*b*) the wearing of dark, protective goggles; and (*c*) the administration of a pill of carbonate of iron twice a day. By June 2nd the ulcer of the right cornea had increased in size, its advancing edge had become irregular, and small vessels were present at its base. There was no actual pain, although the affected eye felt uneasy from time to time. On June 30th there was slight photophobia and watering of the right eye, but no pain. The ulcerated spot in the right cornea was larger, and now presented a raised, sinuous edge, advancing towards the central region. My suspicions with regard to the malignant character of the ulcer were hinted to the patient and explained fully to the medical attendant, Mr. Fenton. On August 4th, the patient complained of an occasional sensation as of a foreign body in the eye; there was, however, little actual pain. Some photophobia was present, but there was no especial redness. The outer and lower part of the right cornea was occupied by a grey, depressed, and uneven ulceration, the advancing edge of which was grey, sinuous, and rather raised. A number of fine vessels, derived from a large trunk in the conjunctiva, ramified over the base of the ulcer. The appearance of the parts is shown in the appended diagram. The lesion, it will

Diagrammatic representation of cornea, showing ulcerated portion and vessels derived from trunk in conjunctiva. Right cornea, August 4th, 1898.

be observed, did not encroach upon the pupillary region of the cornea. The pupil was small and active and there were no signs of iritis. The fundus was in its normal state. Tension was normal. Vision, $\frac{6}{12}$ + 1·5 D. spherical = $\frac{6}{6}$. The glands were not involved. A definite diagnosis was made of rodent cancer on the cornea and operation was advised.

On the following day, under cocaine anæsthesia, the ulcer was thoroughly burnt with the galvano-cautery, special attention being paid to the aggressive margin. The operation (at which Mr. Fenton assisted) was of a somewhat delicate character owing to the care that had to be exercised not to interfere with the clear cornea that lay in front of the pupil. It was followed by pain, œdema and ecchymosis of the eyelids, as well as by marked redness of the globe. On Oct. 13th the lower half or so of the ulcer had cicatrised in a smooth and satisfactory way, but the remainder was uneven, rugous, and permeated by fine vessels. The corneal sensibility as regards both eyes was certainly diminished. This last observation is interesting and bears out Ahlström's statement[2] that such is the case in rodent ulcer of the cornea. Two days later, under local anæsthesia, the galvano-cautery was freely applied to the roughened portions of the cornea. By Feb. 2nd, 1899, the ulcer had completely healed. Right vision, $\frac{6}{18}$. On June 8th the outer third of the right cornea was the seat of a slight opacity, delicate extensions from which crossed the pupillary region. Vision, $\frac{6}{18}$ + 1 D. cylinder axis horizontal $\frac{6}{12}$ iv. With presbyopic correction (+ 3·5 D. spherical) the patient could read slowly the smallest type on Jaeger's test-card. To judge from the refraction, which had formerly been spherical, the operations had slightly altered the curvature of the affected cornea.

Upon inquiry I learn from Mr. Fenton that the patient died on Jan. 12th, 1900, from influenza and failure of the heart. The corneal mischief, however, never recurred, nor did the eyes cause any further trouble.

FOUR CASES OF PUERPERAL ECLAMPSIA.

BY T. B. BROADWAY, M.B., CH.B. GLASG.

THE cases of eclampsia now to be described occurred in my practice during the last six months and presented some points of interest. In the first case the high temperature and the length of time for which it kept up were remarkable, especially as there was nothing septic to account for it.

CASE 1.—In the last week of December, 1899, I was called to a primipara attended by Mr. Goodfellow of Roche. She

was a strong, healthy woman, aged 19 years, and had a normal labour except that Mr. Goodfellow removed the placenta by inserting his hand. She did well for three days, then convulsions came on; Mr. Goodfellow saw her and gave a hopeless prognosis. I was called in on the fifth day; she was then lying comatose, with dilated pupils, a pulse of 140 per minute, and a temperature of 106·2° F.; her mother also stated that she had not passed urine for the last 24 hours. I gave her an hypodermic injection of two grains of pilocarpin nitrate. Shortly before I left, as convulsions again came on, I gave her an enema of one ounce of sulphate of magnesium and one drachm of bromide of potassium as well as douched out her uterus and ordered her mother to keep her on milk and soda-water, feeding her every half hour. On the following day I found her temperature still 106°, but there had been no recurrence of fits and she had passed both fæces and urine in her bed unconsciously. On account of the high temperature I gave her three-grain doses of phenacetin every three hours and put her on the following mixture: solution of perchloride of iron, two drachms; sulphate of magnesium, two ounces; tincture of digitalis, half a drachm; spirit of nitrous ether, two drachms; water to make up eight ounces; one ounce to be taken every four hours. On Dec. 23rd I found her temperature to be 104·8°, and as she was still insensible I asked Dr. Shaw of St. Austell to see her with me. As he thought there might be some uterine mischief, though there was no discharge, I again douched out the uterus with perchloride (1 in 2000). On the following day as her temperature was still 104·4°, I again douched her out with chinosol. On the 25th I found her temperature to be 102·4° and her pulse 120, and for the first time she seemed to notice things—she inquired who I was, and on being asked how she felt she made a complaint of pain in her head and back. I now managed for the first time to obtain some urine and found it loaded with albumin; her recovery, however, from this period was steady, though she was on my hands till the end of January, 1900.

CASE 2.—This patient was a young woman 4 feet 8½ inches in height and very spare. Mr. Goodfellow was attending her; she had been in labour for 48 hours when he telegraphed for me. He told me that she had had several fits and that her labour pains were very unsatisfactory. I found the woman conscious but looking anxious and worn. On examination per vaginam I found the os dilated to the size of half-a-crown. I advised rapid dilatation and instrumental delivery under an anæsthetic. As Mr. Goodfellow agreed we gave her chloroform and delivered her after a little trouble. Her further progress, so far as I am aware, was uneventful.

CASE 3.—I saw this patient for Dr. Shaw of St. Austell. The woman was a multipara, this being her fourth confinement. She had an ordinary labour and was attended by a midwife. On the following day she had convulsions when Dr. Shaw asked me to see her. I found her lying semi-conscious with the muscles of her face twitching; her temperature was 99·4° F.; and her pulse was 110 and irregular. I gave her an injection of half a grain of pilocarpine along with a quarter of a grain of morphine and a mixture containing bromide of potassium and sulphate of magnesium. Since then she has had no more fits, but is still in our hands for albuminuria and anæmia.

CASE 4.—I was called to this patient on June 23rd; on arriving I heard that she had been having labour pains for the last 13 hours but that the friends had sent for me as she had had two or three fits the hour previous to my arrival. The patient was very anæmic. I found her tongue bitten and could elicit no replies to my questions; the os was dilated to about the size of a sixpence. I gave her the following mixture: sulphate of magnesium, one ounce; bromide of potassium, three drachms; water to make up two ounces; one ounce to be taken every three hours. This lessened the number though not the severity of the convulsions, and as on a later visit, some six or seven hours after the first, I found the os dilated to the size of a florin and as she had passed no urine I asked Dr. Shaw to see her with me. We agreed to give an anæsthetic and deliver under it. In this we found no difficulty. We passed a catheter previously to using instruments and drew off half a teacupful of bloody urine. The patient is progressing fairly, though she is not very clear in her answers; there is still a little trouble in her passing urine. Previously to this she was being treated by Dr. Shaw for anæmia and amenorrhœa.

ST. GEORGE'S HOSPITAL.

A CASE OF SUPERNUMERARY TESTIS.

(Under the care of Mr. G. R. TURNER.)

UP to a recent date the possibility of a third testis has been denied. For instance, Mr. Jeremiah McCarthy in Quain's Dictionary, 1882, p. 1606, wrote: "Supernumerary testicles have been described and men not unfrequently believe themselves to be so gifted. The mistake has arisen from the presence of encysted hydroceles or of fatty or fibrous tumours of the cord, or of an old epiplocele. There is no well-authenticated case recorded of the presence of more than two testicles." The same opinion has been expressed in a still more recent work. Lydston,[1] writing in 1899, says: "It is probable that the third testicle is a myth." Yet a few indubitable cases have been recorded in which the supernumerary testis has been removed and examined microscopically. A very remarkable case is described in the *New York Medical Record* of Feb. 23rd, 1895. A recruit of the Eighth Cavalry was found to be possessed of four testicles, three of them being well developed; but in this case, as no operation was performed, no histological examination was made, and the diagnosis may reasonably be considered unsettled.

A healthy-looking child, aged three and a half years, was admitted into St. George's Hospital on July 30th, 1894. On the right side of the scrotum there was an irreducible swelling which was transparent and looked at first sight

A represents the lower (larger) testicle with its hydrocele. B represents the upper testicle with a normal tunica vaginalis. C represents the serous sac in front of the upper part of the cord, with apparently no communication with the peritoneal cavity. *b* and *d* represent the cords of the two testes which seemed to join above.

like a hernia above a hydrocele. The testicle could be felt at the bottom of the scrotum and above this another rounded lump could be distinguished. Mr. Turner cut down on the swelling and separated it from the cord. The upper part was a serous sac full of clear straw-coloured fluid but containing no gut and not communicating with the peritoneal cavity. This cyst was removed. Below it were two testicles; the upper one had a normal tunica vaginalis and a distinct cord of its own and the lower and larger one was in the usual position of the testis with the sac of the tunica vaginalis the seat of hydrocele. This was laid open and its margins were stitched to the skin wound. The boy did well afterwards, though his convalescence was retarded by a whitlow and a portion of the wound healing of necessity by granulation. The left testis appeared to be normal.

[1] Surgical Diseases of the Genito-urinary Tract, p. 921.

Remarks by Mr. TURNER.—An almost exactly similar case was, curiously enough, a fortnight later under the care of Mr. Arbuthnot Lane in Guy's Hospital and has been reported by him.[2] In his case, too, the cord of the supernumerary testis blended above with the spermatic cord but there was no hydrocele. Microscopical examination of the supernumerary testis which Mr. Lane removed showed "well-formed tubules with spermatogenesis proceeding." His patient was a youth, 17 years of age. In the case above related, as in Mr. Lane's case, it would seem that the supernumerary testis is developmentally a subdivision of the larger organ on the same side.

QUEEN'S HOSPITAL, BIRMINGHAM.

FOUR CASES OF CHOREA TREATED WITH LARGE DOSES OF ARSENIC.

(Under the care of Dr. A. H. CARTER.)

IN the successful employment of arsenic in chorea it is now generally agreed that large doses must be administered, and if the initial dose is small it may be slowly or rapidly increased to the maximum. It is now recognised that a large dose of arsenic for a short time is better borne than a smaller dose for a long time. De Renzi[1] has advised that 20 minims of the liquor arsenicalis should be given at first in the case of children and double that amount in the case of adults. These amounts are probably a little excessive as initial doses, but on the whole children stand arsenic well. In all cases much better results are obtainable if the patient is confined strictly to bed. For the notes of the cases we are indebted to Dr. W. Billington, house physician.

CASE 1.—A girl, aged 13 years, was admitted into the Queen's Hospital, Birmingham, on Feb. 13th, 1900. For five weeks she had had choreiform movements and these, in spite of treatment at home, had got worse. Three years previously the patient had acute rheumatism. This was followed by an attack of chorea lasting four weeks. 18 months before admission she had a second attack of chorea. The third and present attack was the most marked and the most resistant to ordinary treatment. The movements were general but not violent, taking the form of persistent "fidgeting." The patient was unable to write or to hold anything in her hands and her speech was slightly affected. The first heart sound was blurred in the mitral area and the apex beat was in the nipple line, but compensation was good. On Feb. 14th the patient was ordered to have 15 minims of solution of arsenic three times a day. The medicine in this case, as in all the others, was given in the middle of a meal in a wine-glassful of water. No signs of intolerance appeared until the 20th, when she vomited once shortly after taking the arsenic. On the 21st the arsenic was stopped altogether, 315 minims of Fowler's solution having been taken in a week. During the time the patient was taking the arsenic she ate and slept well and exhibited no signs of intolerance except the single occasion on which she vomited. A marked improvement in the chorea was noticed on the fourth day and at the end of the week all movement had practically ceased. On Feb. 24th she was allowed to get up and on March 1st she was discharged from the hospital quite cured. She was subsequently under observation for two months and during that time she showed no signs of a relapse.

CASE 2.—A girl, aged six years, was admitted into the Queen's Hospital, Birmingham, on April 23rd, 1900. Chorea had come on for the first time 10 days before admission and quickly became very violent, so much so that her mother was scarcely able to hold her in her arms. The whole body was affected and she was very excited and passionate. There was no very definite history of rheumatism, but the child was said to have had indefinite pains in her legs and thighs for the last six months. These were described as "growing pains." The heart was unaffected. On April 23rd the child was put on 15 minims of solution of arsenic three times a day, and on the 24th this was increased to 18 minims three times a day. There was an immediate and marked improvement and on the 28th the chorea had almost subsided and the patient was eating ravenously and sleeping well without sedatives. No signs of intolerance appeared until the 29th, when she vomited twice after taking her medicine. On the 30th the arsenic was stopped, 354 minims of solution of arsenic having been given in seven days. On May 1st the patient vomited after each meal. The breath was foul, the tongue was furred, the bowels were constipated, and the abdomen was retracted. She was perfectly quiet and seemed to be heavy and dull. An aperient was given together with a simple enema, and the bowels having been freely opened bismuth was given every four hours in 10 grain doses for 24 hours. The vomiting persisted for several days and then stopped, and the patient rapidly convalesced. On May 5th she had a slight twitching of the hands, but this disappeared in a day or two. On the 8th she was allowed to get up and on the 14th she went out of hospital without a trace of chorea having been noticed for a week. She was in hospital for 21 days.

CASE 3.—A married woman, aged 25 years, was admitted into the Queen's Hospital, Birmingham, on April 21st, 1900, with hemichorea of the left side. The chorea had come on a fortnight before admission. 15 weeks previously she had an attack of acute rheumatism and at the time of admission she still complained of obscure pains in her joints, though there were no objective joint changes. She had had three children and at the time of admission was probably two or three months pregnant. She had never had chorea before and only the one attack of rheumatism. The movements were confined to the left arm, the left leg, and the left side of the face, and the patient was unable to hold anything in her left hand on account, as she said, of the jerky movements and a sense of weakness in it. Since the onset of the chorea she had slept badly, had lost her appetite, and had become very excited and emotional. The knee-jerk and plantar reflex on the left side were very lively and a spurious ankle clonus was obtained. The first heart sound was impure, but there were no definite murmurs. On April 22nd the patient was put on 15 minims of solution of arsenic three times a day. On the 24th she vomited once, but three hours after taking her medicine. After this she gradually became worse, the chorea became more marked, and, passing to the other side, affected the whole body. The movements became very violent, the patient got out of bed, shouted, and wept, and did not sleep at all for two days and two nights. When spoken to she answered rationally for a moment, but at once wandered off to something else and at times was very delirious. The bowels were confined, the urine was scanty, and the appetite was very poor. The arsenic was steadily persisted with and on April 28th she began to improve, she slept better, and was much quieter. On the 29th the arsenic was stopped, 315 minims having been taken in seven days. On the 30th the movements had almost ceased and no symptoms of intolerance appeared from first to last. After this improvement was steady and on May 6th all movement had ceased and the patient was able to sew and to read. She ate well and slept well. On the 11th she went out quite well, no movements having been noticed for six days. Ten days later she again reported herself and was then looking much better and stated that she was quite steady and had had no relapse.

CASE 4.—A girl, aged seven years, was admitted into the Queen's Hospital, Birmingham, on May 3rd, 1900, with mild general chorea. The patient had always been excitable and irritable and was "very bright at school." There was no history of rheumatism obtainable. The chorea came on for the first time three weeks before admission, and at the same time her temper became worse and she was very peevish. No improvement followed treatment with small doses of arsenic as an out-patient. On admission the movements were slight, but affected the face and all the limbs. There were no heart murmurs and all the organs appeared to be healthy. On May 6th the child was put on 15 minims of solution of arsenic three times a day. She vomited once on the 7th and twice on the 8th, after which the dose was reduced to 10 minims. She continued to vomit once or twice every day until May 13th, when the arsenic was stopped, 240 minims having been taken in seven days. The vomiting was the only sign of intolerance. During the whole time the patient was taking the arsenic she rapidly improved and on the 13th there were no signs of chorea present. On the 14th she got up and walked about steadily and did some knitting. She was discharged quite cured on the 18th, no movements having been noticed for six days.

Remarks by Dr. BILLINGTON.—These four cases being fairly representative of chorea as commonly met with strongly emphasize the value of arsenic in large doses as a curative remedy and prove the efficiency of Dr. William Murray's

[2] Transactions of the Clinical Society of London, vol. xxviii., 1895, page 59.

[1] American Journal of Medical Science, May, 1896.

method of administration. In none of the cases was any other remedy used; the patient was simply kept in bed on a good diet, with the bed screened off from the rest of the ward. The two points of especial interest which the above cases present are the rapidity with which a cure was affected and the ease with which large doses of arsenic were borne and the insignificance of the symptoms of intolerance. Looking over the hospital records of cases of chorea treated as in-patients I find that the average length of stay is about six weeks, and even after much longer periods many cases have been sent away only partially cured. The average stay in hospital of the above four cases was only 18 days, and all four had shown no signs of chorea for at least five or six days before they were discharged, and all four were allowed to get up and mix with the other patients for several days before going away. This in itself is a very important advantage in a general hospital where there is always great pressure on the beds. With regard to the second point, I am fully in accord with Dr. Murray's statement that large doses of arsenic given for a short space of time in the way he recommends are much less likely to be followed by serious symptoms of poisoning than when it is given in steadily increasing doses over a much longer period of time. It is well known that the latter procedure only brings about appreciable improvement when the dose has become relatively large and the system is brought thoroughly under the influence of the drug. Of course, the treatment adopted in the above cases can only be undertaken when the patient can be kept under close observation and seen at least once a day. In such cases it would seem to be of great service and may with advantage be employed in preference to the persistent administration of small doses of arsenic, the results of which are often very tedious and unsatisfactory.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens. — Residual Urine in Cases of Enlarged Prostate.—Paralysis of the Vertical Movements of the Eye.—Landry's Paralysis.

THE ninth ordinary meeting of this society was held on July 4th, Mr. A. G. MILLER, the President, being in the chair.

Dr. NORMAN WALKER showed two cases of late Syphilides. The first was that of a woman with an affection of the skin over the nose. The diagnosis lay between it being a specific lesion or lupus erythematosus. It was even suggested that it might be a case of lupus vulgaris closely simulating lupus erythematosus. The appearance, however, of a small, sharply punched-out ulcer, the history of a sore-throat, and the rapid development of the affection (within six months), together with the fact that the patient had improved under the administration of iodide of potassium, pointed undoubtedly to its specific origin. The case illustrated the fact that specific lesions might closely simulate any other disease. The second syphilide occurred in a girl, aged nine years. A large number of crusted nummular masses were scattered over the skin of the left side of the body and thigh. Where these had healed deep round scars were left. The treatment in this case consisted in the application of mercury by means of a bib applied to the skin of the chest. No medicine was required to be taken inwardly when it was administered in this way.

Dr. WALKER also showed a man suffering from Ringworm of the Beard. An unusual deformity resulted on the healing of the pustules—a whole crop of tiny little nodules was left on the side of the face and chin.

Mr. J. W. DOWDEN showed a boy, aged five years, after operations for Tubercle of the Upper Ulnar Epiphysis. The abscess had been opened and the sinuses scraped several times. Now the wound was completely healed and perfect movement of the joint persisted.

Dr. LOGAN TURNER showed a case of Asthma in a man associated with Chronic Suppuration in the Left Frontal and Maxillary Sinuses. The first operation consisted in opening the left antral cavity, and later the left frontal sinus was opened through a very small buttonhole-shaped incision towards the inner side of the left eyebrow and curetted. Since these operations there had been no escape of pus into the nose and the asthma had greatly improved. The case was one of double interest—the co-existence of asthma along with disease of the left antrum and frontal sinus.

Dr. WILLIAM RUSSELL exhibited a man, aged 58 years, showing the typical signs and symptoms of Myxœdema—a condition which was much more rarely met with in men than in women. The scalp was completely devoid of hair and the beard and whiskers were scanty. The baldness began to show itself three years previously. The condition of mental lethargy, slowness of speech, apathetic facies, swelling of the eyelids, and malar flush were characteristic.

Dr. WILLIAM RUSSELL showed the following specimens: 1. The Brain and Heart from a case of long-standing Aphasia and Hemiplegia. The patient was a man who was said to have had a sunstroke 12 years previously to his death which was due to phthisis. In the left hemisphere a series of large cysts filled with fluid was present. These had resulted from an embolism in one of the branches of the middle cerebral artery. The heart showed the evidences of an old vegetative endocarditis specially affecting the mitral valve. These vegetations had become quite fibrous. An old aneurysm below the aortic segment was also present. 2. The Brain from a recent case of Aphasia and Hemiplegia. The lesion in this specimen occupied almost the same situation as in the preceding and was quite as extensive. A thrombosis was the cause in this case and this resulted from extensive atheroma of the cerebral vessels. The woman did not die from this disease. Thrombosis or embolism produced the same effect in the brain, a softening of the brain substance resulting, and, if the patients lived long enough, cyst formation resulted.

Dr. PEARSON (for Dr. G. A. GIBSON) exhibited: (1) a specimen showing Patency of the Ductus Arteriosus which was diagnosed during life and proved to exist after death which was due to pneumonia of the right lung; and (2) microscopic specimens of the Filaria Sanguinis in the Proboscis and in the Muscle of the Mosquito.

Mr. HARVEY LITTLEJOHN exhibited: 1. A Heart ruptured by Traumatism. The case was that of a young man who was crushed between the buffers of two railway carriages. The railway company denied any liability as there were no external signs of injury or any fracture of the ribs. The post-mortem examination revealed an extensive rupture of the right auricle fully one and a half inches in length. 2. The Stomachs from two fatal cases of Carbolic Acid Poisoning. One of these resulted from the drinking of 10 ounces of the acid and in this case the stomach showed the ordinary typical appearance, being contracted and leathery and covered with a white putty-like material. In the second case some of the crude carbolic acid used for ordinary disinfection had been drunk out of a beer bottle, and yet though this is much weaker than ordinary carbolic acid the patient died in 15 or 20 minutes. Mr. Littlejohn drew attention to the fact that the proper treatment of all of these cases of poisoning even by the corrosive poisons was the passage of the stomach-tube and the washing out of the stomach. It was better to run the risk of perforating the stomach than the greater risk of death from the action of the drug. 3. The Liver and other Organs from a case of Acute Yellow Atrophy. The case was that of a young woman who had become pregnant and whose lover had refused to marry her. She was seized with intense jaundice and vomiting. Labour ensued and she was delivered by forceps but died 36 hours later. The post-mortem examination showed the presence of numerous hæmorrhages in the skin and organs of the body. The case was one of phosphorus poisoning or acute yellow atrophy (the liver was much atrophied). Tests for phosphorus proved negative, but this did not exclude the possibility of her having swallowed the poison. Her mental condition was such as might have induced her to commit suicide. The uterus was perfectly healthy and presented the normal appearances of the organ at this period after delivery and its condition precluded the idea of acute septicæmia. The stomach was also shown to illustrate the appearance of post-mortem digestion.

Dr. R. A. FLEMING showed: (1) Tuberculous Pericarditis (a rare condition) from a man, aged 40 years, who died from general miliary tuberculosis; (2) Hearts with Patent Foramen Ovale—in one case the opening was very large;

and (3) Fatty Degeneration of the Heart Muscle from a case of Pernicious Anæmia.

Dr. ALEXANDER BRUCE exhibited the Brain from a case of Aphasia. The specimen was from a man who had suffered for a long time from right-sided hemiplegia with aphasia. He was capable of understanding what was said to him but could not read. He spoke volubly but unintelligibly. Being very musical he could sing several tunes perfectly, but the words were gibberish though the rhymes were always conserved. He also retained the power of mimicry to a remarkable extent. The post-mortem examination showed a line of softening running along the whole length of the Sylvian fissure. The superficial portion of the first temporal lobe was conserved and there was only a very slight softening in the angular and supramarginal gyri.

Mr. DOWDEN showed a specimen removed from a child, 14 months old, who had suffered during five days from sickness and vomiting. The left thigh was kept flexed and there was a swelling in the left groin of the size of a hen's egg. The bowels acted properly. On opening the sac the testicle was found with the cord twisted several times. The testicle and part of the cord were removed.

Dr. ALEXANDER JAMES exhibited a specimen from the body of a man who was supposed to have suffered from Abdominal Aneurysm. The deceased was aged 40 years; he was an old soldier, had suffered from syphilis, and had atheromatous arteries. There were a double aortic murmur and a large pulsating tumour over the abdominal aorta. The post-mortem examination showed the presence of a tumour lying over and around one side of the abdominal aorta; the growth was malignant, very vascular, and with many hæmorrhages in it. Dr. James had not made a diagnosis of aneurysm as the aorta seemed a little more fixed than usual and there was no alteration in the pulsations of the femoral arteries as shown by the sphygmograph.

Mr. A. G. MILLER read a clinical note on Residual Urine in cases of Enlarged Prostate. He stated that an enlarged prostate by itself was often enough harmless and was frequently unattended by any symptoms. The danger lay in the residual urine left in the bladder and at present the usual remedy for this was the systematic use of the catheter. Mr. Miller advocated the importance of voluntarily emptying the bladder a second time a few minutes after apparently emptying that organ. He described the case of an active man in whose bladder about three ounces of residual urine were always present. This patient by a systematic voluntary emptying of his bladder by again trying gradually decreased the amount of residual urine until, perhaps, only from two to seven drachms were found retained. He found that he did not require to get up so often during the night and generally improved greatly in health. Mr. Miller thought that usually the bladder was not emptied because a sufficient effort was not made to do so. He asked why an old man with an enlarged prostate did not empty his bladder completely. In old age the muscular power generally diminished and consequently the muscles of the bladder were feebler, and this was associated with an enlarged condition of the prostate. There were two important factors and there might be a third unrecognised factor in this causation—i.e., laziness, impatience, or indifference—which might make the patient stop emptying his bladder as soon as the feeling of distension was relieved. Mr. Miller stated that the great cause of residual urine at first was neglect to empty the bladder; later there might be inability to empty it but neglect was the initial factor. In normal conditions the emptying of the bladder took place without any effort, there being merely the relaxation of certain muscles and the contraction of others, assisted by the atmospheric pressure. The action was partly voluntary and partly involuntary, but the whole process partook more of relaxation than effort, and the relief was pleasant because it was unattended by effort. When a man began to suffer from enlarged prostate, as he had hitherto passed water without effort he consequently did not exert himself. It was much a matter of habit. The rational treatment was to break off the habit at the beginning and to establish the habit of emptying the bladder by a second trial. In advanced cases of prostatic hypertrophy the patient strained to pass water, but atony of the bladder had taken place and the effort was almost useless. The voluntary emptying of the bladder ought to be commenced early. In advanced cases the bladder become hypertrophied, enlarged, and sacculated. The conclusions arrived at were that (1) residual urine was due at first to neglect to empty the bladder; and (2) the accumulation was then due to this becoming a habit. The patient ought to be taught in the beginning of the disease to wait a minute or two after passing water and to try again. He ought to practise this until the residual urine amounted to perhaps only half an ounce. This second trial might be practised twice or thrice daily until the residual urine was got rid of and the bladder regained its tone and resumed its function. This treatment was a safe and easy method and one which might postpone the otherwise almost inevitable period of catheter life.—Dr. ALEXANDER JAMES thought that there was a strong analogy between the condition in the bladder and that found in the lungs. As age advanced the residual air in the lungs went on increasing until emphysema resulted. He stated that a singer must be taught to get rid of this residual air before beginning a new inspiration. He must end a note by compressing his chest and must not begin inspiration until the chest was empty of air.

Dr. ALEXANDER BRUCE read a note of a case of Paralysis of the Vertical Movements of the Eye with Conservation of the Lateral Conjugate Deviation without Ptosis. Cases of paralysis of conjugate deviation with retention of the up-and-down movements of the eyeball were, he said, frequent enough and the reason was well understood. Lateral conjugate deviation was effected through the sixth nucleus which supplied not merely the external rectus muscle of its own side but also indirectly the internal rectus of the opposite side, very much as the reins acted in the hands of a coachman driving a pair of horses. The sixth nucleus was at a considerable distance from the third and fourth nuclei or the other nuclei for the muscles of the eye. A lesion might consequently destroy the sixth nucleus without disturbing the other movements of the eyeball. The opposite condition, however—viz., paralysis of the upward and downward movements of the eye with conservation of the lateral movements—was extremely rare. The cases of this kind described were not more than five in number. *A priori* it might be thought to occur in certain lesions of the middle lobe of the cerebellum. Ferrier stimulated the anterior portion of the middle lobe of the cerebellum and the eyes moved upwards while the head moved backwards. Stimulation of the posterior part of this same lobe caused the eyeballs to be directed downwards and the head forwards. Stimulation still further back caused lateral movements of both eyeballs. A lesion of the upper part of the middle lobe of the cerebellum causing destruction might produce inability to raise the two eyeballs. In one of the cases related a girl lost the power of raising the eyeballs though there was no ptosis. At the post-mortem examination it was found that there was a small tumour at the upper part of the middle lobe of the cerebellum destroying the valve of Vieussens, part of the middle cerebellum lobe itself, and part of the path from the middle lobe; in other words, the centre for the upward movement of the eyeballs was destroyed. The case which Dr. Bruce himself investigated was that of a hard-working female mill-worker, aged about 45 years, who had suffered from what was said to be influenza. She had had some difficulty in walking but had recovered from this. On examination there was found to be a practically complete inability to raise the two eyes in the least and only a very feeble power in depressing the eyes. When asked to raise the eyes she merely looked straight forward; there was no ptosis. When asked to look downwards the eyes descended only very slightly. The lateral movements of the eyeballs were, however, brisk and complete, as was also at first the power of convergence, though this gradually failed. She showed a remarkable unsteadiness. She could not stand erect, but always leaned back strongly on some support as if she were voluntarily pressing backwards. When she was made to sit up straight in bed she always fell back. When made to lean forwards in bed with her hands on her knees she remained so, but whenever she lifted her hands up her back at once straightened itself. The inference was that she suffered from a tumour situated in the cerebellum as described. The patient became gradually more and more unconscious and a greater degree of blindness ensued until death supervened. There was evidently an obstruction to the outflow of cerebro-spinal fluid from the third ventricle backwards. The post-mortem examination showed the presence of a small tumour of about the size of a bean just below the pineal gland and pressing into the third ventricle. The sections through the brain showed a small lenticular tumour right in the middle line and projecting into the hinder part of the third ventricle, and growing not from the optic tract but from

the grey matter around the aqueduct of Sylvius. The symptoms must have been due to a gradual involvement of the external muscles of the eyeball but sparing those for accommodation. The sixth nucleus had been entirely unaffected. The glioma arising in the grey matter had grown backwards along the aqueduct and upwards into the third ventricle.

Dr. ALEXANDER JAMES read a description of a case of Landry's Paralysis and Dr. R. A. FLEMING gave an account of the pathological conditions present in the case. Dr. James stated that when influenza attacked the nervous system specially all kinds of effects might be produced. It might affect special nerves alone. In three patients admitted into Dr. James's ward within a few weeks of one another, all suffering from influenza, a rapidly produced paralysis extending from below upwards was noticed (Landry's paralysis). One typical case was the following. A young woman, aged 23 years, was admitted to the Edinburgh Royal Infirmary on Jan. 31st, 1900, suffering from pains in the head and back and delirium. The influenza had existed for two weeks previously to her admission and she had also suffered from the same disease seven months previously. The headache had been very severe and before her admission she had suffered much from insomnia, crying out constantly and meaninglessly, and being so noisy that her friends thought of sending her to an asylum. She was sensible at times and complained of the globus hystericus. When first examined on Jan. 31st her temperature was 103° F., her pulse was 130, and her respiration was 22. She would not answer questions, but cried out continuously for hours together. She lay on her back and did not move either her legs or arms. The urine and fæces were passed involuntarily. Sensibility to touch and pain seemed normal. The volitional power of arms and legs was lost. There was no distinct evidence of paralysis of the diaphragm. Cheyne-Stokes breathing was present while the girl was awake, but during sleep the breathing was normal. Both superficial and deep reflexes were absent and the power of swallowing was greatly impaired. Later the breathing became more rapid for perhaps half a minute and then quieter. She complained of pain behind the sternum and the upper lip was noticed not to move well as she spoke. Shortly after this her head shook violently, she became wildly delirious, and died soon afterwards. For about 10 days she exhibited the ordinary symptoms of influenza, then a paralysis gradually spreading from the lower extremities to the nervous centres in the medulla ensued.—Dr. FLEMING described the pathological conditions which were present. Excepting an incipient broncho-pneumonia near the root of the left lung no other marked visceral lesion was present. The liver and kidneys showed cloudy swelling; the spleen weighed only four and a half ounces and was acutely congested with a number of small hæmorrhages. In the brain the dura mater was firmly adherent posteriorly. The grey matter was markedly congested and showed general œdema. The pia and arachnoid mater appeared to be normal. There were no degenerations in the columns of the spinal cord and an examination of the cells gave disappointing results. In the medulla the cells were swollen and in the anterior cornua of the cord the multipolar cells were also swollen. The nuclei of these were distinctly eccentric in position and chromatolysis was present in a considerable degree in these swollen cells. The cells in the anterior horns in the lumbar and cervical regions of the cord showed a marked atrophy but stained deeply, and numerous small microscopic hæmorrhages (really microscopic diapedesis of red corpuscles) not visible to the naked eye were present.

THE ROYAL HOSPITAL FOR INCURABLES AT PUTNEY.—By the death of Mr. William Loney of St. Heliers, Jersey, this hospital becomes entitled to the residue of his estate, which it is estimated will eventually amount to about £14,000.

THE PARISH OF ST. GEORGE'S, HANOVER-SQUARE, AND THE ST. PANCRAS SCANDAL.—In consequence of the recent evidence adduced at the official inquiry into this scandal the Relief Committee of St. George's, Hanover-square, has reported that "the question of gratuities was inquired into in August, 1898, by the Schools and Asylums Committee, and in September of the same year by this committee, and on several occasions since the matter has been before other committees of the board, and we are satisfied that so far as this union is concerned no such practice exists."

Reviews and Notices of Books.

Refraction and How to Refract: including Sections on Optics, Retinoscopy, the Fitting of Spectacles and Eyeglasses, &c. By JAMES THORINGTON, A.M., M.D., Adjunct Professor of Ophthalmology in the Philadelphia Polyclinic. With 200 Illustrations, 13 of which are coloured. London: Rebman Limited. 1900. 8vo, pp. 301. Price 7*s.* 6*d.*

THE number of treatises dealing with the subject of refraction since the appearance of Donders's essay on the Refraction and Accommodation of the Eye, which it is the special glory of the New Sydenham Society to have caused to be written and published, is so great, the details have been so thoroughly worked out and presented to the student in so many forms from the elaborate work of Landolt, who seems to have almost exhausted this branch of ophthalmic work and practice, to the pamphlet of a few pages, that it is difficult for any writer, whatever may be his ability, to say much that is new or to do more than refer to such recent improvements or aids to examination as may have come under his notice.

Dr. Thorington's volume commences with a series of definitions of the terms commonly used in optics, giving brief explanations of incident, emergent, reflected, refracted, divergent, and convergent rays; positive and visual foci; the formation of images; the numbering of prisms, and the forms and action of lenses. In regard to the numbering of prisms the author remarks that formerly prisms were numbered by their refracting angles, but that now other methods are in use known as Dennett's and Prentice's methods. The unit or centrad in Dennett's method is a prism that will deviate a ray of light the one-hundredth part of the arc of the radian. The radian is so much of the circumference of a circle as will equal the length of its radius of curvation. This is called the arc of the radian and equals 57·295 degrees. It is divided into 100 parts, and a prism base down at the centre of curvation that will deviate a ray of light downwards just one-hundredth part of the arc is a one centrad. M. Prentice's method, the unit or prism dioptre, is a prism that will deflect a ray of light just one centimetre for each metre of distance, that is the one-hundredth part of the radius measured on the tangent. The various forms of test cards for the determination of the sharpness of vision and the particulars of the mode of examination of the fundus by the direct and the indirect methods are fully given and there is an interesting chart showing at one view all or most of the different forms of clocks that have been proposed for the recognition of astigmia. The whole chapter on Astigmatism is well written, the author describing no less than 15 methods for its discovery. These are: corneal reflex, confusion letters, Placido's disc, stenopæic slit, astigmatic chart, the pointed line test, perforated chart or disc, Pray's letters, Schriner's test, chromo-aberration or cobalt-blue test, Thomson's ametrometer, the ophthalmometer, direct ophthalmoscopy, cylinder lenses, and retinoscopy, and yet with all these mutually supporting or corrective methods mistakes sometimes occur.

The etymology of the various terms in use is given, and in general correctly, but there are some oversights. Thus the derivation of "ametropia" is given ἀ priv., μέτρον, "a measure"; ὄφις, "sight," instead of ὤψ or ὄψις; and on the next page "hyperopia" is derived from ὑπέρ, "over"; ὤφ, eye, and the same error is repeated under "anisometropia." Pince-nez is spelt "pinc-nez." The reader will find some useful information not usually given in similar treatises in regard to bifocal lenses and spectacle frames. The book will prove serviceable to those who are dressers and house

surgeons in ophthalmic wards or to practitioners who wish to familiarise themselves with the modern methods of correcting ametropia.

Commercial Organic Analysis. Vol. II., Part II. By ALFRED H. ALLEN, F.I.C., F.C.S. Third edition, with revisions and additions by the Author and HENRY LEFFMAN, M.A., M.D. Philadelphia. London: J. & A. Churchill. 1900. Pp. 330. Price 14*s*.

IT was inevitable that Mr. Allen's valuable series of volumes on Commercial Organic Analysis should sooner or later have to undergo revision. The progress of analytical chemistry is so rapid as soon to render published methods either obsolete altogether or unsatisfactory in some respect. The work as a whole, indeed, is chiefly valuable because in reality it consists of a trustworthy record of modern analytical processes as applied to those substances which come under the classification of the title of the work. Moreover, Mr. Allen's experience as an analytical and consulting chemist gives him the position of being able to confirm or disprove any given process in vogue. Thus he frequently records his own experience of various analytical processes which when he has found them unsatisfactory he has set to work upon with the view of making them more reliable and perhaps at the same time more expeditious. In this task he has met with considerable success. The volume under notice deals with the very important class of bodies—hydrocarbons, petroleum and coal tar products, asphalt, phenols, and creosote. There are, therefore, chapters in it which relate to the purity of many antiseptics employed in medicine and in sanitation. The valuation of a given antiseptic by bacteriological methods is not described, though we think a short chapter on this subject would have been useful to the practising analyst. The chapter on Petroleum and Shale Products, as well as the chapters on Coal-tar Derivatives, are most valuable. Obviously the present volume deals with the petroleum question in its relation to a legalised flash-point. Mr. Allen points out that all petroleum with a flash-point above 73° F. was by the Act of 1879, and contrary to the 1871 Act, freed from legislative restriction. The purpose of a Bill now (1899) pending in Parliament, he adds, is to substitute the accurate or close test for the inaccurate or open test in the Act of 1871 and to restore the 100° flash-point prescribed by that Act. Though this very accurately and simply defines the position we doubt whether an Act will ever be introduced which will seriously interfere with the sale of petroleum, which is being sold without restriction at the present time. Again, opinion is very much divided as to whether this interference is needed.

The work is one which is indispensable to the analyst, while chemists generally will consult its pages with advantage and confidence.

Micro-organisms and Fermentation. By ALFRED JÖRGENSEN. Translated by A. K. MILLER, Ph.D., F.I.C., and A. E. LEMMHOLM. Third Edition. London: Macmillan and Co. 1900. Pp. 318. Price 10*s*.

WE have before remarked upon the extraordinary economic influence which a study of the habits of micro-organisms is bringing to bear upon several great industries; indeed, it is not too much to say that as our knowledge of fermentative processes has deepened so has sprung up a complete reformation in many industrial processes in which the action of micro-organisms is so intimately concerned. After all, the application of this kind of knowledge is quite old in principle, as must be admitted in the cases of horticulture and agriculture, for, in the last words of the volume before us, "in order to obtain the desired species of plant its seed should be sown free from the seed of all other plants." It was Hansen of the Carlsberg laboratories who first showed that by cultivating a pure yeast a uniform product, whether wine or beer, could be obtained, and the results of this important discovery are now applied on a manufacturing scale in breweries, distilleries, and in the preparation of wines from the grape and other fruit. Nor have Hansen's discoveries stopped here, for pure cultures of lactic acid bacteria have been successfully employed for the souring of cream on a large scale much in the same way as pure yeast has been employed for the manufacture of sound beer. Again, very important experiments have been obtained with encouraging results in tobacco fermentation with the view of producing a definite aroma in tobacco leaves by the addition during fermentation of pure cultures of certain species of bacteria. It is all, in a word, a question of the cultivation of species, the separation of the weed, so to speak, from the true seed. This is the alpha and omega of the work before us. Mr. Jörgensen is a director of the laboratory for the physiology and technology of fermentation at Copenhagen, and his work is therefore closely associated with the classic researches of Hansen of the Carlsberg laboratories. The present volume, it is not surprising to find, is the third edition. The work of revision has been brought into line with modern knowledge. The illustrations are 83 in number, but though true to the original subject they have no special merit of an artistic kind. The work of translation is well done, and a clearer account of the subject we have not had the pleasure of reading. The book is eminently practical in character and thus appeals, as the author states, to chemists, botanists, and biologists, and likewise to those technologists who are engaged in the fermentation industries. Mr. Jörgensen is well known as a most active worker in the direction of the biology of yeasts in its application to industrial processes. His book is therefore not only an excellent text-book for the man who requires to study the subject practically, but it is also educational in another direction, since it contains accounts of the results of his researches during recent years on many interesting aspects of the methods of cultivation. The book opens with chapters on the apparatus used in bio-technical work and an account of the methods of examination. In fine the author grapples with his subject in that clear and intelligible manner which admirably justifies the work being regarded as an excellent laboratory companion on this special branch of bacteriology which might be called "bio-technology."

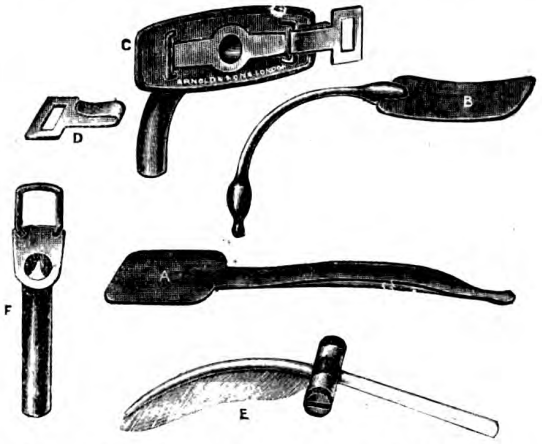
Richter's Organic Chemistry. Edited by Professor R. ANSCHUTZ. Authorised translation by EDGAR F. SMITH, Professor of Chemistry, University of Pennsylvania. Third edition from the eighth German edition. Vol. II., Carbocyclic and Heterocyclic Series. London: Kegan, Paul, Trench, Trübner, and Co., Limited. 1900. Pp. 671. Price 15*s*.

THERE is something to be said in favour of the classification of the carbon compounds which Victor von Richter has adopted in his classic work. In Vol. I, which was reviewed in THE LANCET of May 27th, 1899, p. 1436, the author dealt with the chemistry of the aliphatic series—that is, with the so-called fatty compounds. In the present volume he deals with carbocyclic compounds—that is, compounds containing closed carbon chains or rings. In general these are also isocyclic compounds, because they consist of rings of atoms of one or the same element, as distinguished from heterocyclic compounds which may be regarded as ring skeletons consisting of atoms of various elements. Thus we have a sharp classification of the whole of the compounds known to us which come under the generic term "organic." The alkaloids and a great number of the active principles of plants used in medicine come obviously under consideration in the present volume. The work, however, deals with theoretical rather than with practical considerations, and since von Richter is one of the greatest authorities on classification and constitution the work is one for acceptance. No subject

could be wider than that of organic chemistry, but to deal with it as the author and translator have done within the compass of the comparatively small size of these two volumes is an achievement which has its demerits as well as its merits. Every conceivable space on the pages has been utilised, the paragraphs are very much crowded, and the type generally is very small. On this account the classification of the various compounds does not appear to be as distinct as would have been the case had the volumes been larger and the printed matter less congested. The preparation of the work from the point of view of the printer must have entailed enormous labour and care with proof-sheets. The work, of course, is a standard one, considering the very high position which the author holds as one of the best exponents of the "organic" side of chemical science.

JOURNALS.

The *Veterinarian* for July is an improvement on its predecessor of the previous month, although original articles from English practitioners are still wanting. Summaries are given from colonial reports upon Actinomycosis and Tuberculosis in New Zealand Cattle, the original work having been done by, or under the supervision of, Mr. J. A. Gilruth, M.R.C.V.S. There is an interesting extract from an American journal upon the subject of Oöphorectomy of the Mare, the operation being done per vaginam, the way now almost universally practised. The Glasgow Tramways and Omnibus Company have recently carried out some valuable investigations into the use of mallein as a curative agent in cases of glanders and their conclusions are given in full. Under the "Month's Progress" there are a number of scientific extracts, those bearing upon the latest researches into rabies raising great hope that a rapid method of forming an early and certain diagnosis after the death of the suspected animal can be made. According to work done by M. Nocard of Alfort and also by Cuillé and Vallée of Toulouse the results of the researches of van Gehuchten and Nélis must not at present be absolutely accepted, and whatever opinion is given from a microscopical examination the duty of the veterinary expert is to advise the person bitten to proceed at once to the Pasteur Institute.



THE SANITARY INSPECTORS' ASSOCIATION.—The annual meeting of the western branch of this association held its annual meeting at Dartmouth on July 7th. The mayor read a paper on the Disposal of House Refuse and the medical officer of health (Mr. J. H. Harris), in the course of an interesting address upon the position of sanitary inspectors said that such inspectors should be officials of the Local Government Board, appointed and salaried by that body instead of the local authority, so that they could be thoroughly independent. The mayor afterwards entertained the members at dinner.

HOUSING AND IMPROVEMENT ASSOCIATION.—A conference was held recently in Hulme "to consider the housing question as affected by the past clearance of low-rented houses and the threatened closing by the Sanitary Committee of the Manchester Corporation of many more, because of their alleged unfitness for human habitation." It was attended by many representative people. Resolutions were passed appreciating the action of the City Council in declining to sanction the further closing of houses in Hulme till provision has been made for those displaced, and yet assuring the Sanitary Committee of its support if they will only build as they pull down. The landlord of some of the condemned property brought forward a very familiar argument that there had been no infectious disease in that property for 20 years, and said that "there was too much of this pulling houses down." Such statements are always made where the death-rate is highest. The conference was constituted a permanent Housing and Improvement Association, and may, it is hoped, do useful work.

New Inventions.

NEW TRACHEOTOMY INSTRUMENTS.

THE dilating director A is inserted by the side of the knife before the latter is withdrawn from the trachea; on turning it transversely it both dilates the wound and serves as a director for the tube. The pilot B is original only in its probe point. The outer tube C is shaped like Parker's but has larger wings. The tape holders D are hooked on to the bars of the shield before use; they prevent the tube from being coughed out but allow it free movement. The cleaner E, of stiff plumed feather, is guarded by two little ebonite bars united by rubber rings and adjusted to the length of the tube. It is easily sterilised and cannot reach the

trachea. Where an inner tube is necessary the pattern F is used. Like Durham's it is self-retaining without key. The single handle is placed in the position of greatest mechanical advantage and taken well out of the way. As there is room for a finger on either wing of the outer tube the latter can and should be fixed during the removal of the inner and is then not jogged about in the trachea, nor can it be pulled through the shield. There is nothing about the orifice of the tube or within it likely to catch dirt, every part is readily taken to pieces for cleaning, and the tapes being inserted without any disturbance of the shield are not introduced until all is clean. Messrs. Arnold and Son are the makers.

G. C. GARRATT, M.B. Cantab.,
Assistant Resident Medical Officer at the London Fever Hospital.

AT the meeting of the general committee of the French Hospital, London, on July 12th, Dr. George Ogilvie was unanimously elected physician to the hospital. The committee cordially expressed their appreciation of his services during the past year when acting for Dr. J. S. Keser during his absence abroad.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Wednesday, July 11th, the acting treasurer, Dr. Potter, being in the chair. One new member was elected, the deaths of three members were reported, and three persons had ceased to be members since April last. The death of a widow who had received £35 a year since 1886 was announced. An application for grants for herself and seven children was read from a widow, and grants at the rate of £100 a year were made. The husband, who met with a fatal accident in Australia, had only been elected a member in 1891 and had paid 18 guineas in subscriptions. A sum of £1197 was voted for distribution among 48 widows, 14 orphans, and six recipients from the Copeland Fund. The expenses of the quarter were £44 12*s*. A vote of "God-speed" was passed to Dr. W. S. Church, one of the treasurers of the society, on his appointment on the commission of inquiry into the working of the hospitals in South Africa.

REPORT OF

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY

THE QUESTION OF CONTROL.

I.—THE HISTORY AND DEFINITION OF CONTROL.

The Control of the Metropolitan Water-supply: Introductory; An Ideal Supply of Water for London; Recent Royal Commissions on the Metropolitan Water-supply.—Definition of Control: Control of the Water-supplies in Mediæval London; The Earliest Example of Financial Control; Control with Regard to Smoke; Competition amongst the Water Companies, "Reasonable Charges"; Complaints in Respect of Charges; Complaints in Respect of Quality; New Supply or Efficient Control?

THE CONTROL OF THE METROPOLITAN WATER-SUPPLY.

Introductory.

THERE is perhaps no matter of greater importance to the people of London than the question of their present and future water-supply. During the last few years the East London Waterworks Company have on more than one occasion failed to give an adequate supply to their customers and about two years ago the Lambeth Waterworks Company for a time also failed to give a continuous supply to the people who lived within their Parliamentary area; and although it is provided that the metropolitan water companies shall be fined should they fail to give a continuous supply, in the case of neither of these companies, as far as we are aware, has any serious effort been made to punish them for their neglect of their statutory duties. Some of the other companies have given their customers no reason to complain, but the fact that parts of the London district have been inadequately supplied has once more brought into prominence the whole question of the metropolitan water-supply as it at present exists. In the case of a rapidly spreading city like London, however, a knowledge of the present requirements is not sufficient; it is necessary to look forward to the future.

An Ideal Supply of Water for London.

An ideal supply of water for London would ensure that the quality of the water should be pure and derived from sources beyond the suspicion of pollution; and that the quantity should be adequate not only for domestic supplies, but sufficient to give an unstinted amount for municipal purposes. The public fountains would not be allowed to run dry, the ornamental waters of London (the Serpentine and the ponds in Regent's Park) and the canals would be clear and bright—a state of things which could only be made possible by frequent change of the water, necessarily involving a supply greatly in excess of that which obtains to-day. The Thames, also, should not be allowed to suffer from excessive depletion and it would be far better if its whole natural flow and the whole flow of the Lee were allowed to pass down to cleanse and scour out the lower reaches of the river. Whether London will ever have such a supply in the future the future alone will show. A scheme which would give such results has yet to be devised, and if it were devised it would take many years to carry out.

Recent Royal Commissions on the Metropolitan Water-supply.

The question as to whether the people of London should obtain their supply of drinking water from some pure source at a distance is one upon which at present there is difference of opinion and it is not likely that the question will be settled until the amount of the present sources of supply is definitely known. It cannot at present be said that we are in possession of complete and accurate information on this matter. More than one Royal Commission on the subject of the London water-supply has, it is true, investigated the subject, but it is to be feared that the results of the investigations have not been thoroughly satisfactory, although the time occupied in making them has been very considerable and the expenses incurred have been by no means small. Many of the more thoughtful people of London are regretfully coming to the conclusion that the members of the present Government who have been responsible for the appointment of the last two Royal Commissions on the metropolitan water-supply have adopted this method of proceeding rather with a view to evade for the time their own responsibilities in matters which have been "under investigation"; and the somewhat cynical remarks on the alcohol question lately made by Lord Salisbury with reference to the Licensing Commission Report have given countenance to this opinion. It is also feared that the choice of the members of a Royal Commission is sometimes made rather with a view to avoid criticism than with any hope that the members selected will seriously do their best to get to the bottom of the problem which they are called upon to solve. On such occasions "vested interests" are by no means always ignored.

Lord Balfour's Commission reported on the quantity of water which was available in the valleys of the Thames and the Lee. Unfortunately the figures which were given to the Commission have, as we shall see, proved to be erroneous. It therefore follows that the report on the available quantity of water is not entirely reliable.

Lord Llandaff's Commission were instructed to investigate the financial expediency of purchase of the metropolitan water companies' undertakings and were asked to advise as to whether it would be well for the water-supply to be placed under the care of one or more authorities, and if so, as to

what authority should be empowered to undertake the management, should the purchase of the present companies' undertakings be considered advisable. They were asked to report also as to whether any additional measures of control of the water undertakings were needed.

A great part of the evidence given at Lord Llandaff's Commission had reference to the expediency of purchase and dealt with the financial history and the present state of the eight metropolitan water companies. Anyone who may read and digest all the evidence carefully must entertain grave doubts as to the expediency of purchase from the point of view of the water consumer, even if, as Lord Llandaff's Commission assumed, the present sources of supply will be sufficient for many years to come. It may also be pointed out that the metropolitan water companies, as far as they themselves are concerned, are entirely opposed to an amalgamation of the different businesses into one organisation; that is to say, the engineers and directors of the companies who are naturally the persons most intimately acquainted with the working of their own businesses are decidedly of opinion that they are better carried on as separate entities than they would be under one central management. This in itself is a strong argument against placing the present undertakings under one management. The opinion of the engineers and directors of the water companies is formed with a thorough knowledge of all the facts of the case and there are many details of administration and difficulties of organisation known to them which are not by any means common knowledge and which are probably neither appreciated nor even suspected by some of the people who think that under any circumstances the mere possession of a number of different businesses by one Board could ensure unity of management. "Unity of management" is a well-sounding phrase, but a well-sounding phrase will not alter physical facts. The possession of the water mains of two companies by the same Board will not cause unity of pressure of the water conducted through the mains. The pressure in the pipes will depend on the same physical causes whoever be the owner of the pipes. The fact that the metropolitan water companies differ in the details of their method of supply renders it physically impossible that "unity of management" could be of any value or could become an effective fact without a great many changes in the plant and apparatus used for the distribution of the water. A real "unity of management" as understood by those who glibly use the phrase, therefore, must necessarily involve a large outlay—a point which they apparently have not grasped with equal tenacity. A careful study of the Llandaff report throws very great doubt on the financial expediency of purchase even if the Thames and Lee be able to give a sufficient supply of water. The report shows that the Commission had, as a matter of fact, considerable doubt as to the future cost of the London water-supply, and that they did not disguise from themselves the real danger of financial disaster which might ensue to the buyer. This fact is shown clearly enough by the powers for obtaining money which they suggested should be conferred on the Board which they proposed should be empowered to carry on the work of the present undertakings. No consideration of the question of a new Water Board would be complete if no account were taken of the fact that the representatives of the metropolitan counties are entirely opposed to the formation of such a Board and to the purchase of the present water companies' undertakings. There is no doubt that very considerable opposition would arise if any attempt were to be made by the Government to carry out the recommendations of the Llandaff Commission for the formation of such a Board. The question is a large and intricate one, and up to the present time there is a lack of accurate information in regard to the water-bearing capacities of parts which are within the area of Water London. It would be a waste of time for Parliament in the present state of knowledge to attempt any legislation dealing financially with the water-supply of London. It by no means follows that nothing at all should be done. On the contrary, it is highly desirable that information which is at present lacking should be collected and weighed and it is necessary that this should be done before any final decision is arrived at with regard to the future sources of the water-supply of London. This information can only be obtained by instituting additional measures of control over the metropolitan water companies. Up to the present time the companies' witnesses who have appeared before the Royal Commissions have been extremely reticent and no information has been given with regard to the effect of pumping on the wells of the companies.

DEFINITION OF CONTROL.

In the evidence which he gave before Lord Llandaff's Commission Mr. Whitmore, Member of Parliament for Chelsea, who was also a member of the London County Council, said that he had given a great deal of attention to the question of the metropolitan water-supply, and in the course of a lengthy oration he said that he had never been able to understand what control as applied to water companies means. In the following pages an attempt has been made to explain what measures of control at present exist and what new measures of control are desirable.

Briefly stated control as applied to the metropolitan water companies means that some superior authority should have statutory powers to enforce obligations which have been imposed by law on the companies which supply the water. Powers of control already exist in regard to the financial management of the water companies, in regard to the quantity and quality of the water supplied by them, and in regard to the charges they are allowed to make to their customers. Additional powers of control have been recommended by the Balfour and Llandaff Commissions, but up to the present time the Government has made no attempt to translate these recommendations into statutory life.

Control of the Water-supplies in Mediæval London.

The origin and history of the control exercised over the supply of water for the people of London can be only briefly sketched. Until the reign of Elizabeth the citizens of London obtained their water either from the river, from springs or wells, or from the public conduits. The conduits were the property of the City of London, and regulations were made by the Corporation in regard to the time and manner in which water could be obtained from them. The keepers of the conduits were removeable at the discretion of the civic authorities. A small amount of water was sold to brewers and other tradesmen, and a few noblemen had "quills" or small pipes laid on from the public mains for the supply of their houses, and for this accommodation it does not appear that any charge was made. The greater part of the water was distributed gratuitously but those who wanted it had either themselves to carry it away from the public conduits or to buy it from those who made it a business to carry it round to private houses. Briefly, at this time the control of the water-supplies in the City was in the hands of the Corporation of London.

At the end of the sixteenth century (1581) a lease of one of the arches under London Bridge was granted to an engineer for the purpose of putting up a water-wheel to pump from the Thames. This venture was subsidised by the city authorities and the water was supplied to some of their conduits. The profit of the undertaking, which was a private enterprise, was derived from the rents paid by those to whose houses the water was laid on. The price paid was a matter of bargain. Early in the seventeenth century (1613) the water of the New River was brought to London and was soon afterwards distributed to the houses of those who were willing to pay for it. In this case, also, the price paid was purely a matter of arrangement between the buyer and the seller. The city conduits were still supplied with water but the amount was inadequate, and James I., who was the chief shareholder in the New River undertaking, did not encourage either the introduction of new supplies or the repair of the conduits which belonged to the City and which served to bring the water from the distant springs. The public supplies fell off, and finally the Great Fire hopelessly damaged the leaden pipes and cisterns.[1]

The Earliest Example of Financial Control.

The earliest example of control which occurs in the history of the metropolitan water companies is probably a section of an Act of the Chelsea Company (8 Geo. I., cap. 26) which prohibited dealing in the shares until the works undertaken

[1] The conduits, according to a contemporary authority, "stood like so many little but strong forts to confront and give check to the great enemy; and as enemies are wont to deal with castles, thought impregnable, by attempting to carry them by storm, so went the fire to work with these little castles of stone, which were not easy for it to burn down ..... and spoiled them, or almost spoiled them, by melting the leaden channels through which their supplies of water came."

by the company were completed, "and for preventing all sinister practices or abuses of this Act ..... it shall not be lawful for any person or persons whatsoever having any stock or share in the said undertaking to transfer or assign the same before or until such time as water be brought into the grand reservatory or reservatories intended to be at or near Oliver's Mount."

Control with Regard to Smoke.

It may not be without interest to note that one of the earliest measures of control contained in an Act of a metropolitan water company had reference to the consumption of smoke. The Grand Junction Waterworks Company was incorporated (51 Geo. III., cap. 169) to supply the parish of Paddington and the parishes and streets near, and a section of the Act provided that every furnace used by the company should consume its own smoke and every chimney should have its shaft at least 130 feet above the ground level, and that the smoke issuing therefrom should not at any one time exceed the quantity of smoke usually issuing from the chimneys of 24 fires for domestic uses.[2] It was provided that any chimney or furnace belonging to the company which broke this regulation might be dealt with as a common nuisance. The Act contained also provisions forbidding the erection of a furnace or steam-engine within a quarter of a mile of Edgware-road without the sanction of Mr. Edward Berkeley Portman. Another provision in the Act had reference to the water rents chargeable by the company to the effect that tenants on the Bishop of London's estate at Paddington were to have a reduction of 10 per cent. on the average rates paid by other customers.[3]

Competition amongst the Water Companies: "Reasonable Charges."

During the early part of the present century there was keen competition between the new companies which had then lately arisen—the West Middlesex and the Grand Junction—and the older companies—the London Bridge, the New River, the York Buildings, and the Chelsea. The new companies offered water at higher pressure and at a reduced price. The amount charged was a matter of bargain. The West Middlesex Company according to the terms of their Act were allowed only to make reasonable charges, but the meaning of the word "reasonable" was left to the discretion of the company. During the height of the competition there was an acrimonious correspondence between the New River Company and the West Middlesex Company (1811–12), but soon afterwards (1815) a Bill was introduced into Parliament for the amalgamation of these two businesses. The metropolitan water companies had found it inconvenient to undersell one another and they ultimately agreed amongst themselves to partition the town between them so that there should be no longer any active competition.

Complaints in respect of Charges.

The amount charged for water was immediately raised by all the companies and between the years 1810 and 1821 the increase in the water rentals amounted to about 25 per cent. A Parliamentary committee which investigated the complaints which were made on this score reported that in every instance the rentals were left solely to the agents of the different companies to charge as they should think fit and that the charges were not regulated either by the quantity of water consumed or by the distance to which it was conveyed. After the reception of the Parliamentary report in 1828 Mr. Peel, who was at the time Home Secretary, suggested that if the public were dissatisfied a new company would arise. He did not wish to encourage such a speculation; he did not indeed think it would be well for the Government to interfere or to appoint engineers to suggest the manner in which individuals (water company shareholders) should manage their own property.

Complaints in respect of Quality.

The prices charged by the companies formed the first ground of grievance which the public thought they had against them, but at a later period the quality of the water aroused somewhat general disapproval. The spread of cholera was distinctly traced to the water-supply and when this fact was at length thoroughly realised there was a general feeling that the public had not been well treated.

New Supply or Efficient Control.

The question arose as to whether a new supply should be obtained and placed under the Board of Health, but finally the action of Parliament was decided in accordance with advice given by Lord Seymour (1852) whose opinion was that all it behoved Parliament to do was to provide for an efficient control over the companies so that water should be supplied good in quality, sufficient in quantity, and at a cheap rate. The companies, he said, had better be left to act separately or in conjunction as they should find best.

The Metropolis Water Act was passed in the year 1852. Under this enactment provisions were made with regard to the quantity and quality of water which the companies were called upon to supply and during the same year arrangements were made by which within a certain time the intakes of the companies from the Thames were to be moved to points higher up the river than the places from which the water had previously been taken.

After the year 1852 the next important general Act which dealt with the metropolitan water-supply was that of 1871 which provided for the appointment of a water examiner and altered the regulations under which a continuous service of water could be insisted on by the inhabitants of the metropolitan area. In the year 1887 an Act was passed giving increased power to local authorities in regard to questions of control. These regulations are given fully in the pages which follow.

II.—THE EXISTING STATUTORY PROVISIONS FOR CONTROL.

Obligations of Water Companies to Lay Mains and to Provide and Supply Water for Domestic Purposes: Supply of Water for Domestic Purposes; Provisions as to Water Rates; Provisions as to the cutting off Supplies; Constant Supply for Domestic Use; Constant Supply for Municipal Purposes.—Control now exercised in respect of Quality, &c.: Quality and Quantity, Regulations concerning Reservoirs and Aqueducts; Water Examiner; Prevention of Waste, Misuse, and Contamination of Water; Accounts and Audit of the Water Companies' Businesses; Limitation of the Dividends of the Companies.

THE statutory provisions with regard to control of the metropolitan water companies undertakings have reference to—1. The obligation to lay mains and to provide and supply water throughout their districts. 2. The obligation to supply the water in sufficient quantity and of good quality. 3. The financial management of the undertakings and the amount which they are allowed to charge for the water which they supply.

In the account which follows of the provisions for control which now exist a statement given by Mr. E. A. Bonnor-Maurice to the Llandaff Commission has been closely followed and the sections of the general Acts of Parliament in which the provisions with regard to control are contained are in most cases quoted *in extenso*. In the case of the private Acts of the companies references are given to the sections of the Acts which bear on the subject, and in all these cases either the exact words or the gist of the section referred to are given. The interpretation of the Acts put in by Mr. Bonnor-Maurice gave rise to a little discussion between the members of Lord Llandaff's Commission and some points which were raised will be briefly noted in their proper place.

[2] It need hardly be said that since the date of that Act (1811) the regulations made with regard to smoke have been made very much more stringent.

[3] The Bishop of London was the owner of land from which water was formerly obtained by the Corporation of London for the supply of the City. The spring was situated near the Bayswater-road.

OBLIGATIONS OF WATER COMPANIES TO LAY MAINS AND TO PROVIDE AND SUPPLY WATER FOR DOMESTIC PURPOSES.

The companies are required to cause main pipes to be laid down and pure and wholesome water to be brought to every part of the district within the limits of supply on the requisition of so many owners and occupiers in that part of the district so that the aggregate amount of water-rates payable by them annually at rates specified in the Acts of Parliament of the respective companies shall be not less than one-third part of the expense of providing and laying down such pipes: provided that no such requisition shall be binding on the companies unless those owners and occupiers severally execute agreements binding them to take a supply for domestic purposes for three consecutive years.

The sections in the private Acts of the metropolitan companies which refer to the laying of mains and the provision of water are not identical. The Kent Company have no Act which contains specific provisions bearing on these matters. In the case of the other companies the provisions are as follows:—

The *New River* (15 & 16 Vict., cap. 160, sec. 34), the *Grand Junction* (15 & 16 Vict., cap. 157, sec. 40), the *Southwark and Vauxhall* (15 & 16 Vict., cap. 158, sec. 47), and the *West Middlesex* (15 & 16 Vict., cap. 149, sec. 33) companies have each and all the following statutory provision:—

The company shall cause main pipes to be laid down and pure and wholesome water to be brought to every part of the district within the limits of this Act, whereunto they shall be required by so many owners or occupiers of houses in that part of the district, as that the aggregate amount of water-rate payable by them annually at the rates specified in this Act shall not be less than one-tenth part of the expenses of providing and laying down such pipes: Provided always that no such requisition shall be binding on the company unless such owners or occupiers shall severally execute an agreement binding themselves to take such supply of water for three successive years at least: Provided also that the company shall not be bound to provide or lay down any communication pipes for any such supply of water except at the expense of the persons requiring the supply: Provided also that the company shall not be bound to furnish any such supply of water or lay down any pipe for such purpose in any part of the district which part is, for the time being, supplied with water by any other company.

The *Chelsea Company* (15 & 16 Vict., cap. 156, sections 64 and 65) and the *East London Company* (16 & 17 Vict., cap. 166, sections 57 to 61) are each controlled by the following regulation:—

That the company shall cause main pipes to be laid down, and pure and wholesome water to be brought to every part of the district within the limits of this Act, whereunto they shall be required by so many owners or occupiers of houses in that part of the district as that the aggregate amount of water-rate payable by them annually at the rates specified in this Act shall be not less than one-tenth part of the expense of providing and laying down such pipes: Provided always that no such requisition shall be binding on the company unless such owners or occupiers shall severally execute an agreement binding themselves to take such supply of water for three successive years at least: Provided also that the company shall not be bound to provide or lay down any communication pipes for any such supply of water except at the expense of the persons requiring the supply: Provided also that the company shall not be bound to furnish any such supply of water or lay down any pipe for such purpose in any part of the district which part is, for the time being, supplied with water by any other company.

That if for twenty-eight days after demand in writing made to the company and tender made of an agreement signed by such number of owners or occupiers as aforesaid, to take and pay for a supply of water for three years or more, the company shall refuse or neglect to lay down pipes in the manner hereinbefore directed, and to provide such supply of water as aforesaid, they shall forfeit to each of such owners and occupiers the amount of rate which he would be liable to pay under such agreement, and also the further sum of forty shillings for every day during which they shall refuse or neglect to lay down such pipes or to provide such supply of water: Provided always that the company shall not be liable to any penalty for not supplying water if the want of such supply shall arise from frost, unusual drought, or other unavoidable cause or accident.

The case of the *Lambeth Company* is somewhat different. Under the Waterworks Clauses Act, 1847, sections 35 and 36, the following clauses (which are not incorporated by the other companies) are in force:—

The undertakers shall provide and keep in the pipes to be laid down by them a supply of pure and wholesome water sufficient for the domestic use of all the inhabitants of the town or district within the limits of the special Act, who, as hereinafter provided, shall be entitled to demand a supply, and shall be willing to pay water rate for the same, and such supply shall be constantly laid on at such a pressure as will make the water reach the top storey of the highest house within the said limits, unless it be provided by the special Act that the water to be supplied by the undertakers need not be constantly laid on under pressure, and the undertakers shall cause pipes to be laid down and water to be brought to every part of the town or district within the limits of the special Act, whereunto they shall be required by so many owners or occupiers of houses in that part of the town or district as that the aggregate amount of water rate payable by them annually at the rates specified in the special Act shall be not less than one-tenth part of the expense of providing and laying down such pipes: Provided that no such requisition shall be binding on the undertakers unless such owners or occupiers shall severally execute an agreement binding themselves to take such supply of water for three successive years at least.

If, for twenty-eight days after demand in writing, made to the undertakers, and tender made of an agreement signed by such number of owners or occupiers as aforesaid, to take and pay for a supply of water for three years or more, the undertakers shall refuse or neglect to lay down pipes in the manner hereinbefore directed and to provide such supply of water as aforesaid or as provided by the special Act, they shall forfeit to each of such owners or occupiers the amount of rate which he would be liable to pay under such agreement, and also the further sum of forty shillings for every day during which they shall refuse or neglect to lay down such pipes or to provide such supply of water: Provided always that the undertakers shall not be liable to any penalty for not supplying water if the want of such supply shall arise from frost, unusual drought, or other unavoidable cause or accident.

During the sixtieth sitting of Lord Llandaff's Commission (which was held on March 14th, 1899) a rather interesting discussion arose with regard to the interpretation of this clause. The late Major-General Scott asked Mr. Bonnor-Maurice whether he could tell him if a water company having neglected to provide storage to meet the ordinary increase of supply which is always required in a dry summer and if in that particular summer there happened to be an unusual drought the company would be exempted under this section of the Act on a default of that kind. Mr. Bonnor-Maurice said he thought that the question would be decided according to the facts of the case. The Act said frost or unusual drought. If the company could show it was frost or unusual drought which caused the deficiency they would be exempt. "But," he added, "this question is one which is at the present moment before the law courts in the form of an application by the Hackney Vestry against the East London Company." Major-General Scott asked the witness to state what the question exactly was and the witness, in reply, said it was as to whether if the company could by reasonable forethought have foreseen the drought they ought to have prepared for it. Mr. Pember, who appeared as counsel for the East London and some of the other water companies, interposed by asking whether there would not be the question as to the exercise of reasonable foresight and if the company had taken reasonable precaution whether that plea would avail against the words of the section of the Act which had been quoted. Major-General Scott said that a company might be so much short in their provisions that they might in an ordinary dry summer fail to give a constant supply for six weeks perhaps. Assuming, then, that an unusual drought occurred in that year or in any year which caused them to fail in their supply for four months instead of six weeks, could they plead an unusual drought? Mr. Bonnor-Maurice replied that he thought the plea might be admissible, but in that case the *onus probandi* would be thrown upon the company to show that the want of the usual supply arose from unusual drought. The company were bound to take reasonable precautions to meet as far as they could what could be reasonably expected in the future. If they failed to do that there might be some question as to whether they would be liable; but if, on the other hand, they could distinctly bring themselves within the section that the want of supply arose from unusual drought, the exemption would apply. Major-General Scott said that in the supposititious case that he gave the assumption was that the reservoirs of the company were so deficient that six weeks' failure would have arisen as the result of an ordinary drought in an ordinary summer. Mr. Bonnor-Maurice said that he imagined that the company would not be able to plead that the deficiency of supply arose from an unusual drought if the failure occurred under such conditions. Lord Llandaff remarked that if he understood Major-General Scott aright the question was, supposing a company had failed in exercising reasonable forethought and then there supervened one of the statutory extraordinary contingencies, did the supervention of frost, drought, or unusual accident excuse them from what would be otherwise an undoubted default? In short, Major-General Scott was suggesting that a case of supervening drought might cover, as it were, and excuse the preliminary default. Mr. Pember said that if he were the judge he should say that he was not going to try the issue of what would have happened if there had not been a drought. There was no drought, and what they wanted was the real exciting cause. Mr. Pope, Q.C., who appeared for the New River Company and the Southwark and Vauxhall Company, pointed out that the words of the section "or other unavoidable cause or accident" referred, he thought, to the provisions expressed. It must be a default which could not reasonably

be provided against. For example, in the case of a culvert which a company were bound to provide under a railway the culvert must be sufficient to take all reasonably anticipated floods, but if a flood greater than ever before known should arise and sweep away the whole of the culvert there was no liability on the part of the company because the accident was unavoidable, inasmuch as the flood was greater than it was reasonably necessary to provide against. Mr. Pember said that he might have to argue a case like that which had been referred to by Major-General Scott, and Lord Llandaff remarked that he thought the Commission could not decide these nice questions on points of law.[4]

In their report, however, the Commission advise (p. 71) that "it should be made clear that 'frost, unusual drought, or unavoidable accident,' would not excuse a failure of supply, if it be shown that the failure occurred because the works of the company were not in an efficient condition and have not sufficient reserve capacity of supply."

Supply of Water for Domestic Purposes.

At the request of any owner or occupier (who shall have laid the communication pipes between the companies' mains and the premises to be supplied, and paid or tendered the water rate) of any house in any street within the limits of supply in which any pipe of a company shall be laid, or of any person who is entitled to demand a supply of water for domestic purposes, the company is required to furnish to such person a sufficient supply of water for his domestic purposes, at the rates specified in the Acts of Parliament of the respective company.

The special obligations of the metropolitan water companies to furnish a supply of water to the inhabitants of their authorised areas of distribution are as follows:—

Lambeth (11 Vict., cap. 7, sec. 37).—And be it enacted that the company shall, at the request of the owner or occupier of any house or part of a house in any street within the limits of this Act in which any pipe of the company shall be laid, or of any person who, under the provisions of this Act or any Act incorporated therewith, shall be entitled to demand a supply of water for domestic purposes, furnish to such owner or occupier or other person a sufficient supply of water for their domestic uses, at the rates hereinafter specified.

Chelsea (15 & 16 Vict., cap. 156, sec. 60).—That the company shall, at the request of the owner or occupier of any house in any street within the limits of this Act in which any pipe of the company shall be laid, or of any person who, under the provisions of this Act or any Act incorporated therewith, shall be entitled to demand a supply of water for domestic purposes, furnish to such owner or occupier or other person a sufficient supply of water for their domestic purposes, at the rates hereinafter specified.*

New River (15 & 16 Vict., cap. 160, sec. 35).—That the company shall, at the request of the owner or occupier of any house or part of a house in any street within the limits in which any pipe of the company shall be laid, or of any person who, under the provisions of this Act or any Act incorporated therewith, shall be entitled to demand a supply of water for domestic purposes, furnish to such owner or occupier or other person, a sufficient supply of water for domestic purposes at the rates hereinafter specified.*

Southwark and Vauxhall (15 & 16 Vict., cap. 158, sec. 53).—That the company shall, at the request of the owner or occupier of any house or part of a house occupied as a separate tenement in any street within their limits in which any main or service pipe of the company shall be laid, or of any other person who, under this Act, shall be entitled to demand a supply of water for domestic purposes, furnish to such person, by means of communication pipes and other necessary and proper apparatus, to be provided, laid down, and maintained at the cost of such person, a sufficient supply of water for his domestic purposes, at a rate per centum per annum on the annual value of the house not exceeding five pounds.*

West Middlesex (15 & 16 Vict., cap. 159, sec. 39).—That the company shall, at the request of the owner or occupier of any house in any street within the limits of this Act in which any pipe of the company shall be laid, or of any person who, under the provisions of this Act or any Act incorporated therewith, shall be entitled to demand a supply of water for domestic purposes, furnish to such owner or occupier or other person a sufficient supply of water for their domestic purposes at the rates hereinafter specified.*

Grand Junction (15 & 16 Vict., cap. 157, sec. 46).—That the company shall, at the request of the owner or occupier of any house in any street within the limits of this Act in which any pipe of the company shall be laid, or of any person who, under the provisions of this Act or any Act incorporated therewith, shall be entitled to demand a supply of water for domestic purposes, furnish to such owner or occupier or other person a sufficient supply of water for their domestic purposes at the rates hereinafter specified.*

East London (16 & 17 Vict., cap. 166, sec. 74).—That the company shall, at the request of the owner or occupier of any house, or any part of a house occupied as a separate tenement, in any street within their limits in which any main or service pipe of the company is or shall be laid, or of any person who, under this Act shall be entitled to demand a supply of water for domestic purposes, furnish to such person by means of communication pipes and other necessary and proper apparatus to be provided, laid down, and maintained at the cost of such person, a sufficient supply of water for his domestic purposes, at a rate per centum per annum on the annual value of the house not exceeding .....*

Kent (27 & 28 Vict., cap. 146, sec. 28).—The company shall, at the request of the owner or occupier of any house or part of a house in any street in which from time to time any pipe of the company is laid, or of any person who, under the provisions of this Act is entitled to demand a supply of water for domestic purposes, furnish to him a sufficient supply of water for domestic purposes at rates not exceeding the following .....*

* In every case the maximum legal water-rate which may be charged is named in the Act.

It is, however, provided that the companies shall not be bound to supply water under pressure at any higher level than the levels fixed by the Acts of Parliament of the respective companies.

The maximum height to which each of the metropolitan water companies is bound to supply water, and the Act of Parliament under which each provision is made is given below.

Chelsea (15 & 16 Vict., cap. 156, sec. 54).—To a height which is ensured by a pressure in a reservoir, the level of which shall not be less than 148 feet above Trinity high-water mark.

East London (Sch. B of the Metropolis Water Act, 1871, and sec. 15 of the Metropolis Water Act, 1852).—40 feet above level of pavement nearest the point at which supply shall be required.

Grand Junction (15 & 16 Vict., cap. 157, sec. 41).—150 feet above the level of high-water mark at Vauxhall Bridge, computed according to the Trinity standard.

Kent (Sch. B of the Metropolis Water Act, 1871, and sec. 15 of the Metropolis Water Act, 1852).—180 feet above Trinity high-water mark.

Lambeth (11 Vict., cap. 7, sec. 35).—To 150 feet above Trinity high-water mark of river Thames.

New River (15 & 16 Vict., cap. 160, sec. 28).—70 feet in height from the pavement of the street in which the house supplied is situate.

Southwark and Vauxhall (15 & 16 Vict., cap. 158, sec. 48).—150 feet above the level of high-water mark at Vauxhall Bridge, computed according to the Trinity standard.

West Middlesex (15 & 16 Vict., cap. 159, sec. 34).—200 feet above the level of Trinity high-water mark at Hammersmith Bridge, computed according to the Trinity standard.

The companies are not bound to furnish a supply of water or to lay down any pipe for that purpose in any part of a district which is for the time being supplied with water by any other company, but this exemption does not apply in the cases of the Kent and Lambeth companies.

The statutory provisions with regard to the supply of water are contained in the Waterworks Clauses Act (1847) and are as follows (sections 43 and 53):—

If, except when prevented as aforesaid, the undertakers neglect or refuse to fix, maintain, or repair such fireplug, or to furnish to the Town Commissioners a sufficient supply of water for the public purposes aforesaid, upon such terms as shall have been agreed on or settled as aforesaid, or if, except as aforesaid, they neglect to keep their pipes charged under such pressure as aforesaid, or neglect or refuse to furnish to any owner or occupier entitled under this or the special Act to receive a supply of water during any part of the time for which the rates for such supply have been paid or tendered, they shall be liable to a penalty of ten pounds and shall also forfeit to the Town Commissioners, and to every person having paid or tendered the rate, the sum of forty shillings for every day during which such refusal or neglect shall continue after notice in writing shall have been given to the undertakers of the want of supply.

Every owner and occupier of any dwelling-house or part of a dwelling-house within the limits of the special Act shall, when he has laid such communication pipes as aforesaid, and paid or tendered the water-rate payable in respect thereof, according to the provisions of this and the special Act, be entitled to demand and receive from the undertakers a sufficient supply of water for his purposes.

Provisions as to Water-rates.

The rates chargeable by the water companies are fixed by the Acts of Parliament of the companies and are based upon the annual value of the premises, with fixed maximum charges in addition for water-closets, baths, &c. These rates and charges vary in the case of the different companies. Outside the metropolis the rates have been charged upon the annual value of the premises; in cases of difference of opinion as to what is the annual value the matter may be determined by two justices (section 68 of the Waterworks Clauses Act, 1847). This provision is as follows:—

The water-rates, except as hereinafter and in the special Act mentioned, shall be paid by and be recoverable from the person requiring, receiving, or using the supply of water, and shall be payable according to the annual value of the tenement supplied with water, and if any dispute arise as to such value the same shall be determined by two justices.

A dispute which arose as to the interpretation of this section led to the celebrated case of Dobbs *versus* The Grand Junction Water Works Company. (L. R. 9 App. Cas. 49; 53 L. J. Q. B. 50; 49 L. T. (N.S.) 541; 32 W. R. 432; 48 J. P. 5.) It was decided that the value of the premises was to be ascertained on the same principles as those which apply to the ascertainment of the rateable value for the purposes of

[4] Minutes of Proceedings taken before the Royal Commission on London Water Supply, Tuesday, March 14th, 1899. Sixtieth day. Dyson and Co., 9, St. George-street, Westminster, S.W. Pp. 470–473. These are the shorthand notes taken at the sittings of the Llandaff Commission, and supplied to the Commission (gratuitously) and to the water companies and "parties interested" on payment of a proportional part of the expenses. The notes were at the sittings of the Commission commonly referred to as the "County Council Print."

the poor-rate. In the year 1885 the Water Rate Definition Act (48 & 49 Vict., cap. 34, sec. 1) was passed and it was enacted that the words "annual value of the tenement supplied with water" shall mean "rateable value as set from time to time by the local authority as duly constituted."

Owners of property in the districts supplied by the East London, Grand Junction, Kent, Southwark and Vauxhall, and West Middlesex companies are, under the special Acts of those companies, liable to pay the water-rate where the value of the premises does not exceed £20 per annum. In the case of the Chelsea, the New River, and the Lambeth companies owners of property are liable to pay the water-rate where the value of the premises does not exceed £10 per annum. This is provided by the Waterworks Clauses Acts, 1847, section 72 of which is as follows:—

The owners of all dwelling houses or parts of dwelling houses occupied as separate tenements, the annual value of which houses or tenements shall not exceed the sum of ten pounds, shall be liable to the payment of the rates instead of the occupiers thereof; and the powers and provisions herein or in the special Act contained for the recovery of rates from occupiers shall be construed to apply to the owners of such houses and tenements; and the person receiving the rents of any such house or tenement as aforesaid from the occupier thereof, on his own account, or as agent, or receiver for any person interested therein, shall be deemed the owner of such house or tenement.

Water-rates are payable quarterly in advance under a provision of the Waterworks Clauses Act, 1847, of which section 70 is as follows:—

The rates shall be paid in advance by equal quarterly payments, in England or Ireland at Christmas Day, Lady Day, Midsummer Day, and Michaelmas Day, and in Scotland at Martinmas, Candlemas, Whitsuntide, and Lammas, and the first payment shall be made at the time when the pipe by which the water is supplied is made to communicate with the pipes of the undertakers or at the time when the agreement to take water from the undertakers is made.

Payment of water-rates may be enforced by cutting off the supply and recovery of the amount due in a court of summary jurisdiction. This is provided under the Waterworks Clauses Act, 1847, section 74 of which is as follows:—

If any person supplied with water by the undertakers, or liable as herein or in the special Act provided to pay the water-rate, neglect to pay such water-rate at any of the said times of payment thereof, the undertakers may stop the water from flowing into the premises in respect of which such rate is payable by cutting off the pipe to such premises or by such means as the undertakers shall think fit, and may recover the rate due from such person, if less than twenty pounds, with the expenses of cutting off the water and costs of recovering the rate, in the same manner as any damages for the recovery of which no special provision is made are recoverable by this or the special Act; or if the rate so due amount to twenty pounds or upwards the undertakers may recover the same with the exception of cutting off the water by action in any court of competent jurisdiction.

Provisions as to Cutting Off Supplies.

In the cases in which the owner and not the occupier is liable whether by law or by agreement with the water company to pay the water-rate the companies are not allowed to cut off the water-supply for non-payment of water-rate, but they may sue the owner or, failing him, the occupier, and the rate may become a charge on the premises. Section 4 of the Water Companies (Regulation of Powers) Act, contains this provision.

"Every water company which is a trading company supplying water for profit and to which any of the provisions of the Waterworks Clauses Act, 1847, have been or shall be made applicable by any special Act or provisional Order confirmed by Parliament."

Water companies are required to give notice in writing to the sanitary authority within 24 hours of their having cut off the water-supply to any inhabited dwelling-house, subject to the payment of a penalty of £10. The Public Health (London) Act, 1891, section 49 (54 & 55 Vict., cap. 76), provides that—

1. Where a water company may lawfully cut off the water-supply to any inhabited dwelling-house and cease to supply such house with water for non-payment of water-rate or other cause, the company shall in every case, within twenty-four hours after exercising the said right, give notice thereof in writing to the sanitary authority of the district in which the house is situated.
2. Any company which neglects to comply with the foregoing provision shall be liable to a fine not exceeding ten pounds, and it shall be the duty of the sanitary authority to take proceedings against any company in default.
3. This section shall apply to every water company which is a trading company supplying water for profit.

Unless an incoming tenant shall have agreed with the outgoing tenant who is in default in respect of the water-rate, to pay such arrears the companies are not allowed to require payment of arrears of water-rate from the incoming tenant as a condition of supply, but must supply water to the incoming tenant upon being required by him so to do. This is provided for by the Metropolis Water Act, 1871, section 48, which is as follows:—

In case any consumer leave the premises where water was supplied to him without paying to the Company the rate due from him, the Company shall not require from the next tenant of the premises payment of the arrears so left unpaid, unless the incoming tenant agreed with the defaulting consumer to pay the arrears, but the Company shall, notwithstanding any such arrears, supply water to the incoming tenant, on being required by him so to do.

The obligation under which the companies are placed to lay mains and supply water may be enforced in a court of summary jurisdiction by the recovery of penalties, at the suit of the owner or occupier, under the provisions of the Waterworks Clauses Act, 1847, and the Acts of Parliament of the companies, or by the recovery of penalties on the order of the Railway and Canal Commission under the Metropolis Water Act, 1897, at the suit of the consumer or of the local authority; a local authority may also aid a consumer to take proceedings and may pay any legal expenses (if necessary).

Constant Supply for Domestic Use.

The metropolitan water companies are required to provide and keep throughout their water limits a constant supply of pure and wholesome water sufficient for the domestic purposes of the inhabitants within such limits constantly laid on at such pressure as will make the water reach the top storey of the highest houses within such limits (but not exceeding the levels prescribed by the Acts of Parliament of the respective companies) and, subject to the Acts of Parliament of the respective companies as amended by the Metropolis Water Act, 1871, to give to the inhabitants a constant supply of water for domestic purposes. By the Metropolis Water Act, 1871, the companies are, under a penalty of £200 and a further penalty of £100 per month, bound to provide a "constant supply" of pure and wholesome water within the area of the metropolis if required by the metropolitan authority or by the Local Government Board at such times as may be fixed by the Local Government Board who may in certain conditions extend such times, but the companies are not liable to penalties if the want of supply arises from frost, unusual drought, or other unavoidable cause or accident.

The statutory provisions are contained in the Metropolis Water Act, 1871 (34 & 35 Vict., cap. 113), sections 7, 8, 11, 13, 15, 16, 44, and 45). These provisions are as follows:—

Subject to the provisions of this Act, every Company may, and from and after the expiration of eight months from the passing of this Act every Company shall, when required so to do, in the manner directed by this Act, provide and keep throughout their water limits, or throughout such parts of such limits as they may be required in manner aforesaid, a constant supply of pure and wholesome water sufficient for the domestic purposes of the inhabitants within such water limits, constantly laid on at such pressure as will make such water reach the top storey of the highest houses within such water limits (but not exceeding the level prescribed by the special Act) of such Company (which supply is in this Act referred to as a "constant supply"); and every such Company shall, subject to the provisions of the special Act as the same are amended by this Act, give and continue to give to such inhabitants a constant supply for domestic purposes in manner prescribed.

The Metropolitan Authority shall, whenever they are of opinion that there should be in any district a constant supply, make application to the Company within the water limits in which such districts is situate, requiring a constant supply in such district, and any Company may without any such application propose to the Metropolitan Authority to give a constant supply in any district.

It shall be lawful for the Board of Trade at any time to require a constant supply to be provided in any district by the Company within the water limits of which such district is situate upon complaint made, and in case it appears to such Board, after due inquiry:

That the Metropolitan Authority refuses to make or unreasonably delay making application for such constant supply, or

That by reason of the insufficiency of the existing supply of water in such district, or the unwholesomeness of such water in consequence of its being improperly stored, the health of the inhabitants of such district is, or is likely to be, prejudicially affected.

Where a constant supply is required in any district and the Company is unable from want of funds or other cause of any kind to execute all the necessary works within the time prescribed by this Act the Board of Trade, if they think fit, may extend the time for the giving of such supply generally or may extend the time and direct such supply to be given at different times in succession to the several parts of such district in such a manner as may be found most convenient: Provided that application be made by the Company for such extension of time within one month after the notice referred to in the last preceding section has been served upon them.

Notwithstanding anything in this Act a Company shall not be subject to any liability for not giving a constant supply if the want of such supply arises from the frost, unusual drought, or other unavoidable cause or accident.

Any Company which violates, refuses, or neglects to comply with any of the preceding provisions of this Act shall be liable to a penalty not exceeding two hundred pounds and to a further penalty not exceeding one hundred pounds for every month during which such violation or refusal or neglect to comply with the said provisions continues after they shall have received notice in writing from the Board of Trade (Local Government Board) to discontinue such violation, refusal, or neglect as aforesaid.

Every penalty incurred by any Company by reason of non-compliance

with any of the provisions of this Act shall go and belong to the Metropolitan Authority within the jurisdiction of which the same has been incurred, and may be sued for and recovered by such Metropolitan Authority in any court of competent jurisdiction for the recovery of any ordinary simple contract debt of the like amount, and shall be paid and applied as such Metropolitan Authority shall from time to time direct.

Every such penalty shall be borne and paid (to the satisfaction of the auditor appointed as in this Act provided) exclusively by and out of the divisible profits of the Company by whom the penalty is incurred, and by way of reduction of dividend.

Except as is by the next preceding section expressly provided, all penalties under this Act may be sued for and recovered in the "Court of Summary Jurisdiction."

The metropolitan authority is, in the metropolis, the London County Council; in the city, the corporation; in the urban sanitary districts outside the metropolis, the urban sanitary authority; and in rural parishes, the vestries.

Under the Metropolis Water Act, 1897, the statutory area of constant supply is extended so as to include the whole of the authorised area of the companies (Water London). The council of the county or of the county borough are the "Metropolitan Authority" empowered to exercise the control for which provision is made in the Act.

These obligations may be enforced in the usual way (see sections 44 and 45 of the Act of 1871) as to recovery of penalties, and in addition the remedies under the Metropolis Water Act, 1897, may be put in force by any consumer, or local authority, by obtaining through the Railway and Canal Commission the determination of any question of interest to water consumers as to the quantity or quality of water supplied or the charges therefor. (See sections of the Metropolis Water Act, 1897, quoted in the next column.)

Constant Supply for Municipal Purposes.

By the Waterworks Clauses Act, 1847, sections 37 to 43, the companies are under the obligation to fix fire-plugs within certain prescribed distances, and unless prevented as aforesaid to keep in all pipes to which a fire-plug is fixed a sufficient quantity of water for: (1) cleansing sewers and drains; (2) cleansing and watering streets; (3) supplying public pumps, baths, and washhouses; and (4) extinguishing fires.

The supply for public purposes is settled, in case of dispute with the local authority, by two justices or in London by a stipendiary magistrate (section 37). The supply for extinguishing fires is, and always has been, supplied without payment; the London County Council have succeeded to the duties of the late Metropolitan Board of Works and within the metropolis they make regulations as to the form, dimension, &c., of fire-plugs under the Metropolitan Fire Brigade Act, 1865, section 32, and as to the form, dimensions, position, number, &c., of the hydrants, under the Metropolis Water Act, 1871, section 34, which is as follows:—

Section 32 of the Metropolitan Fire Brigade Act, 1865, shall operate, subject and according to the provisions following; (that is to say,)

In that section and in this provision the term "fire-plug" and the term "plug" shall include hydrant and all other apparatus necessary or proper in connexion with the Company's pipes for supply of water in case of fire:

Where a Company give a constant supply in any part of their water limits they may, if they think fit, give notice thereof to the Metropolitan Board of Works:

If the Metropolitan Board of Works do not within two months after receipt of any such notice specify, as regards that part of the Company's water limits, what plugs for supply of water in case of fire, at what places, of what dimensions, and in what form they require the Company to provide, then, at any time after the expiration of that time, the Company may, if they think fit, provide in and for that part of their water limits such plugs for supply of water in case of fire, at such places, of such dimensions, and in such form as to the Company seem necessary or proper:

Thereupon, as regards that part of the Company's water limits, the Company shall be deemed to have fully discharged all obligations imposed on them by the said section 32:

All plugs provided by a Company in pursance of this provision may, for the purposes of the fire brigade, be used as if they had been provided on the requisition of the Metropolitan Board of Works under the said section 32.

The providing of plugs by a Company under this provision shall be at the expense of the Metropolitan Board of Works, and the costs, charges, and expenses of the Company in or about the providing of the same shall be paid to the Company by the Metropolitan Board of Works, on demand, out of their general rate, and in default may be sued for and recovered, with costs, by the Company in any court of competent jurisdiction for the recovery of any ordinary simple contract debt of the like amount.

The provisions of the Metropolis Water Act, 1897, apply an additional method of procedure in case of the failure of any statutory duty by the companies, and facilitate the investigation of any cause of complaint whether in regard to the quality or quantity of the water or of the charges imposed. (Section 1, sub-sections (1), (2), and (3).)

The sections of this Act which apply to these matters are given below.

Any water consumer or any local authority may complain to the Railway and Canal Commission that any of the metropolitan water Companies has failed to perform some statutory duty of the Company, and the Commission may hear and determine that complaint and if satisfied of such failure order the Company within the time limited by the order to fulfil the duty, and may, if they think fit, by any such order, impose any penalty for such failure which can be imposed under any Act, and enforce any such order in like manner as any other order of the Commission.

If at any time complaint as to the quantity or quality of the water supplied by any of the metropolitan water companies for domestic use is made to the Railway and Canal Commission by any water consumer or local authority, the Commission may hear and determine such complaint, and if satisfied that the complaint is well founded, may order the Company, within such reasonable time as is specified in the order, to remove the ground of such complaint, and may enforce such order in like manner as any other order of the Commission, and may award damages to the complainant.

All enactments relating to the Railway and Canal Commission (except section 2 of the Railway and Canal Traffic Act, 1894, which restricts the power to award costs) shall, with the necessary modifications, apply to the Railway and Canal Commission for the purpose of their jurisdiction under this Act.

CONTROL NOW EXERCISED IN RESPECT OF QUALITY, QUANTITY, FINANCE, &C.

The Metropolis Water Acts, 1852 and 1871, conferred to the Board of Trade powers of control in respect of the quality and the quantity of water to be supplied and in respect to the financial proceedings of the companies. These powers, under the Public Health Act, 1872, were transferred to the Local Government Board. Under the Metropolitan Water Act, 1897, the Railway and Canal Commission are empowered to make orders to compel the companies to perform any of their statutory duties.

New sources of supply.—**No company is allowed to resort to any new source of supply until it has given three months' previous notice in writing to the Local Government Board, who may appoint an inspector to visit and inspect any sources specially authorised by Parliament, and to see whether the directions contained in the special Act have been complied with. In regard to new sources not specially authorised by an Act of Parliament, the Board's inspector must examine whether they are capable of supplying good and wholesome water for domestic purposes. On his report the Local Government Board are to certify their approval or disapproval of sources not so specially authorised; and if disapproved the company is not allowed to use the new source.**

Quality and Quantity: Regulations concerning Reservoirs and Aqueducts.

Provision is made in sections 2, 3, and 4 of the Metropolis Water Act, 1852, that only covered reservoirs shall be used for the storage of filtered water at any place within five miles of St. Paul's Cathedral; and that covered aqueducts only shall be used for the filtered water and for the filtration of water (other than that derived from wells) used for domestic purposes.

The following are the statutory provisions of control in regard to the filtration, storage, and conveyance of water; they apply to all the metropolitan companies.

Efficient filtration.—**Every company shall effectually filter all water supplied by them within the metropolis for domestic use before the same shall pass into the pipes for distribution, excepting any water which may be pumped from wells into a covered reservoir or aqueduct without exposure to the atmosphere, and which shall not be afterwards mixed with unfiltered water. (15 & 16 Vict., cap. 84, sec. 4.)**

Storage reservoirs.—**Every reservoir within a distance in a straight line from St. Paul's Cathedral, in the City of London, of not more than five miles in which water for the supply for domestic use of the metropolis or any part thereof is stored or kept by any company shall be roofed in or otherwise covered over. (15 & 16 Vict., cap. 84, sec. 2.)**

Pipes and aqueducts.—**No water shall be brought or conducted within the metropolis by any company for the purpose of domestic use otherwise than through pipes or through covered aqueducts, unless the same shall be afterwards filtered before distribution. (15 & 16 Vict., cap. 84, sec. 3.)**

These provisions may be enforced by a penalty of £200 and £100 per month after receipt of notice from the Local Government Board or by order of the Railway and Canal Commission.

Under the provisions of the Metropolis Water Act of 1852, on the receipt of a complaint from 20 householders as to the quality or quantity of water for domestic use, the Local Government Board may appoint a competent person to inquire and report, with powers to inspect and examine

the waterworks. If he reports that the complaint is well founded the Local Government Board are authorised to give notice to the company, which must, within reasonable time, remove the grounds of complaint.

The provisions of the Metropolis Water Act, 1852, which bear on these points, are given below.

If at any time complaint as to the quantity or quality of the water supplied by any Company for domestic use be made to the Board of Trade (Local Government Board) by memorial in writing signed by not less than twenty inhabitant householders paying rents for and supplied with water by the Company, it shall be lawful for the Board of Trade (Local Government Board), at any time within one month after the receipt of such complaint, to appoint a competent person to inquire into and concerning the grounds of such complaint, and to report to the Board of Trade (Local Government Board) thereon.

The person so appointed as aforesaid shall, within three days after such appointment, give notice thereof in writing to the Company, and after such notice as aforesaid, he shall have power to inspect and examine the waterworks of the Company, and to inquire into and concerning the grounds of such complaint; and the Company and their officers shall afford all reasonable facilities for such inspection, examination, and inquiry.

Any person obstructing such inspector in the due prosecution of such inspection, examination, or inquiry, shall forfeit and pay any sum not exceeding ten pounds.

If after receipt of such report it shall appear to the Board of Trade (Local Government Board) that the said complaint is well founded, the Board of Trade (Local Government Board) shall give notice thereof in writing to the Company.

After the receipt of such notice the Company shall, and they are hereby required, within a reasonable time to remove the ground of such complaint.

Any Company which shall violate, refuse, or neglect to comply with any of the provisions hereinbefore contained shall forfeit to Her Majesty the sum of two hundred pounds, and the further sum of one hundred pounds for every month during which they shall continue to violate or to refuse or neglect to comply with the same after they shall have received notice in writing from the Board of Trade to discontinue such violation, refusal, or neglect as aforesaid.

The above powers of the Act of 1852 were extended in the year 1871, and now the Local Government Board may on their own initiative institute an inquiry into the quality of water at any time, with similar powers as if a complaint had been made. The Metropolis Water Act, 1897, extends these powers as to complaint to any consumer or local authority, and any local authority may aid any consumer in its district by prosecuting a defaulting company.

The following provisions of the Metropolis Water Act (1871) refer to these matters:—

The Board of Trade (Local Government Board) may at any time, if and when they think fit, appoint a competent person to inquire into, and report on, the quality of the water furnished by any Company, notwithstanding that no complaint has been made and signed by twenty inhabitant householders, as prescribed by section 9 of "The Metropolis Water Act, 1852," and sections 10, and 11, and 13, and the other provisions of that Act shall apply in every respect as if such person were appointed under section 9 of that Act and as if any matter reported to the Board of Trade (Local Government Board) as requiring alteration on the part of a Company had been the subject of a complaint by such householders as aforesaid.

Water Examiner.

Under section 36 of the Act of 1871 the Board of Trade appointed a Water Examiner—a competent and impartial person with full powers to examine the water, and to see whether it is efficiently filtered, and furnish reports, with information as to the supply, works, &c., of each company. These reports are circulated, and anyone interested can obtain them either directly or through any bookseller from Eyre and Spottiswoode, East Harding-street, Fleet-street, E.C. The reports are issued monthly and the price is 6*d.* per copy.

The provisions under which the Water Examiner is appointed are as follows:—

There shall be a Water Examiner, being a competent and impartial person, from time to time appointed by and removeable by the Board of Trade (Local Government Board), who shall from time to time, in such manner as the Board of Trade (Local Government Board) direct, examine the water supplied by any Company in order to ascertain whether or not the Company have complied with the requirements of section 4 of the Metropolis Water Act, 1852, and shall from time to time report the results of his several examinations to the Board of Trade (Local Government Board); and the Board of Trade (Local Government Board) shall send a copy of every such report to the Company to which the same relates, and the Company may, if they think fit, on each occasion of such examination be represented thereat by some officer, but such officer shall not interfere in the examination.

There shall be paid to such Water Examiner such remuneration by the Companies and in such proportions as such Board appoints.

Constant supply.—It has already been stated that the local authority, the Local Government Board, or any water consumer, can enforce a constant supply (see p. 187).

The method of dealing with a peccant water company has, it should be noted, been greatly simplified by the Metropolis Water Act, 1897. Under the provisions of this Act any aggrieved water consumer can appeal directly to the Railway and Canal Commission.

Prevention of Waste, Misuse, and Contamination of Water.

Such regulations as may be found necessary for the prevention of waste, misuse, undue consumption, or contamination of water, and as to prescribing the necessary fittings, have to be made by any company with the approval of the Local Government Board, and on failure by any company to make or, when required by the metropolitan authority or by 10 consumers, to alter or repeal such regulations, the Board may appoint a competent impartial person of engineering knowledge and experience to make, alter, or repeal such regulations or to advise as to their being sufficient, and on his recommendation the Local Government Board may make, alter, or repeal, and call in special expert assistance, and the metropolitan authority has the right to be heard before any regulations are made, repealed, or altered, and notice thereof has to be given to such authority. The companies are required also to keep and supply maps of their district and pipes.

The statutory provisions for these regulations are contained in the Metropolis Water Act, 1852, section 26, and the Metropolis Water Act, 1871, sections 17, 18, and 19, which are as follows:—

It shall be lawful for any Company from time to time with the approval of the Board of Trade to make such regulations as shall be necessary or expedient for the purpose of preventing the waste or misuse of water and therein amongst other things to prescribe the size, nature, and strength of the pipes, cocks, cisterns, and other apparatus to be used and to interdict any arrangement and the use of any pipes, cocks, cisterns, or other apparatus which may tend to such waste or misuse as aforesaid.

Every Company shall, within six months after the passing of this Act, make regulations for the purpose for which regulations may be made under the authority of section 26 of the Metropolis Water Act, 1852, and the provisions of that section shall apply also to the preventing of undue consumption or contamination of water.

Any Company, if it thinks fit, or if requested so to do by the Board of Trade, may repeal or alter any of the regulations made for the purposes aforesaid, or make new regulations instead of any of the same.

In case any Company does not make regulations within the time specified in this Act, or in case any Company, on being requested in writing by the metropolitan authority, or by any ten consumers of the water supplied by that Company, to repeal or alter any of the regulations for the time being in force, or to make new regulations instead of any of the same, refuses so to do, the Board of Trade may, if they think fit, appoint a competent and impartial person of engineering knowledge and experience to report to them as to such regulations as may be necessary for the execution of this Act, or as to the expediency of altering or repealing such regulations, or of making new regulations, in conformity with such request as aforesaid, and on the report of such person the Board of Trade may make such regulations, repeal, or alterations as they think fit.

Accounts and Audit of the Water Companies' Businesses.

Every company is required to make up and forward to the Local Government Board, to the town clerk of the City of London, and to the clerk to the County Council, and to keep for sale to any applicant, statements of account in the form and containing the particulars prescribed by the Local Government Board, and that Board is required to appoint a competent and impartial auditor (at such remuneration to be paid by the companies as the Board may fix) to investigate the accounts, ascertaining, distinguishing, and certifying share and loan capital, the amount of new capital, and its expenditure, and if *bonâ fide* made for the purpose of the undertaking. If he should find the accounts incorrect in principle or in detail he may require correction before giving his certificate, and the payment of future dividend is to be suspended until the correction be made and the certificate is given. The companies are bound under penalties of £10 for every default to comply strictly with these provisions and to give all facilities, access to books, and to produce vouchers and afford information to the auditor. Any questions between him and the companies may be referred to arbitration. And subject to this provision the companies are required to abide by the direction and determination of the auditor.

The provisions in regard to the accounts and audit are contained in the Metropolis Water Act, 1871, sections 37 to 42, which are as follows:—

Every Company shall, on or before the thirty-first day of July in each year, fill up and forward to the Board of Trade and to the town clerk of the City of London, and to the Metropolitan Board of Works, and to the vestry clerk of each parish within which water is supplied by each Company respectively not within the City of London, a statement of account, made up to the end of their financial year than last passed, in such form and containing such particulars as may from time to time be prescribed by the Board of Trade.

Each Company shall keep copies of such statement at their office for one year after the date thereof and sell the same to any applicant at a price not exceeding one shilling for each such copy.

In case any Company make default in complying with any of the provisions of this section they shall be liable to a penalty not exceeding ten pounds for each day during which such default continues.

There shall be an auditor of the accounts of the Companies, being a competent and impartial person, from time to time appointed by and removeable by the Board of Trade.

There shall be paid to such auditor such remuneration by the Companies and in such proportions as such Board appoints.

The auditor shall, with all practicable speed after the passing of this Act, investigate the accounts of the Companies, and ascertain and certify the amounts of their capitals, distinguishing share from loan capital, and shall ascertain and certify the capital of each Company and shall from time to time, as new capital shall be expended, in like manner ascertain and certify the amount of such new capital that has been *bond fide* expended for the purposes of the undertaking. Notwithstanding anything in this Act, the auditor shall not investigate the accounts of any Company antecedent to the date mentioned in that behalf in relation to such Company in the Schedule C to this Act annexed.

The auditor shall once in every half-year audit the accounts of the Companies.

If he finds the accounts correct he shall certify the same, but if in any instance he finds the accounts of any Company incorrect in principle or in detail, he shall require such Company to correct such accounts in such manner as he thinks right, and no future dividend shall in any case be declared by any Company until their accounts are certified by the auditor; provided that the suspension of a dividend under this section shall not operate until after the expiration of nine months from the date of the audit.

Each Company shall, during as well as subsequent to the close of that half-year to which the accounts relate, give to the auditor, his clerks, and assistants, access to the books and documents of such Company, and shall, when required, furnish to him and them all vouchers and information requisite for the purposes of the audit, and shall afford to him and them all facilities for the proper execution of his and their duty; and any Company making default in complying with any of the provisions of this section shall, for every such default, be liable to a penalty not exceeding ten pounds.

If any Company think themselves aggrieved by any act or determination of the auditor, the matter in difference shall be referred to the determination of an arbitrator agreed on between such Company and the auditor, or, in default of agreement, appointed, on the application of either party, by the Lord Chief Justice of the Court of Common Pleas; and the reference shall be subject and according to the provisions of the Common Law Procedure Act, 1854: and the decision of the arbitrator shall be final and conclusive; and, subject to this provision, such Company shall observe and abide by the directions and determinations of the auditor.

Limitation of the Dividends of the Companies.

By the Waterworks Clauses Act, 1847, the companies (except in the case of the New River Company) can only pay dividends on their ordinary share capital at the rate prescribed by their special Acts and in no case beyond a maximum of 10 per cent. per annum. They are, however, allowed to make up back dividends, and all surplus profits, subject to the formation of a reserve fund of limited amount, must be applied in making a reduction of the rates charged to the consumers for water. The West Middlesex Company having paid all the back dividends due to the shareholders and having formed a reserve fund are required at the present time to make a reduction in the rates they charge. This reduction, which is a statutory necessity, is noted on the water-rate bills sent out by the company and is called a "rebate"—a word possibly liable to the misinterpretation that the customer is enjoying some beneficent liberality on the part of the company.

The provision in regard to the limitations of the dividends, which may be paid by the companies is contained in the Waterworks Clauses Act, 1847, sections 75 to 82, which are as follows:—

And with respect to the amount of profit to be received by the undertakers when the waterworks are carried on for their benefit be it enacted as follows:—

The profits of the undertaking to be divided among the undertakers in any year shall not exceed the prescribed rate, or where no rate is prescribed they shall not exceed the rate of ten pounds in the hundred by the year on the paid up capital in the undertaking, which in such case shall be deemed the prescribed rate, unless a larger dividend be at any time necessary to make up the deficiency of any previous dividend which shall have fallen short of the said yearly rate.

If the clear profits of the undertaking in any year amount to a larger sum than is sufficient after making up the deficiency in the dividends of any previous year as aforesaid to make a dividend at the prescribed rate the excess beyond the sum necessary for such purpose shall from time to time be invested in Government or other securities and the dividends and interest arising from such securities shall also be invested in the same or like securities in order that the same may accumulate at compound interest until the fund so formed amounts to the prescribed sum, or if no sum be prescribed to a sum equal to one-tenth part of the nominal capital of the undertakers, which sum shall form a reserve fund to answer any deficiency which may at any time happen in the amount of divisible profits or to meet any extraordinary claim or demand which may at any time arise against the undertakers, and if such fund be at any time reduced it may thereafter be again restored to the said sum, and so from time to time as often as such reduction shall happen.

Provided always that no sum of money shall be taken from the said fund for the purpose of meeting any extraordinary claim unless it be first certified in England or Ireland by two Justices and in Scotland by the Sheriff that the sum so proposed to be taken is required for the purpose of meeting an extraordinary claim within the meaning of this or the special Act.

When such fund shall, by accumulation or otherwise, amount to the prescribed sum or one-tenth part of the nominal capital, as the case may be, the interest and dividends thereon shall no longer be invested, but shall be applied to any of the general purposes of the undertaking to which the profits thereof are applicable.

If in any year the profits of the undertaking divisible amongst the undertakers shall not amount to the prescribed rate such a sum may be taken from the reserved fund as, with the actual divisible profits of such year, will enable the undertakers to make a dividend of the amount aforesaid and so from time to time as often as the occasion shall require.

In England or Ireland the Court of Quarter Sessions and in Scotland the Sheriff of such county may, on the petition of any two water-rate payers within the limits of the special Act, appoint some accountant or other competent person, not being a proprietor of any waterworks, to examine and ascertain at the expense of the undertakers the actual state and condition of the concerns of the undertakers and make report thereof to the said Court at the then present or some following sessions, or to the Sheriff (the amount of such expense to be determined by the said Court or Sheriff), and the said Court or Sheriff may examine any witnesses upon oath touching the truth of the said accounts, and the matters therein referred to, and if it thereupon appear to the said Court or Sheriff that the profits of the undertakers for the preceding year have exceeded the prescribed rate the undertakers shall, in case the whole of the said reserved fund has been and then remains invested as aforesaid and in case dividends to the amount hereinbefore limited have been paid, make such a rateable reduction in the rates for water to be furnished by them as in the judgment of the said Court or Sheriff shall be proper, but so as such rates when reduced shall insure to the undertakers, regard being had to the amount of profit before received, a profit as near as may be to the prescribed rate.

Provided always that if, in the case of any petition so presented, it appear to the said Court or Sheriff that there was no sufficient ground for presenting the same the said Court or Sheriff may, if they or he think fit, order the petitioner to pay the whole or any part of the costs of or incident to such petition (the amount thereof to be determined by the said Court or Sheriff), and the costs so ordered to be paid shall be recoverable in the same way as damages are recoverable under this or the special Act.

If the undertakers shall, for seven days after being required to produce to the said Court or Sheriff or to the said accountant or other person as aforesaid, any books of account or other books, bills, receipts, vouchers, or papers relating to their pecuniary affairs refuse or neglect to produce such books, bills, receipts, vouchers, or papers, they shall forfeit the sum of one hundred pounds for every such refusal or wilful neglect and the further sum of ten pounds for every day during which such refusal or wilful neglect shall continue after the expiration of the said seven days, such respective penalties to be recovered by any person who will sue for the same, with full costs of suit, in any of the Superior Courts.

Issue of New Capital by the Companies; the Sinking Fund Clause.

The companies are now compelled to issue any new capital authorised by their recent private Acts under the "Auction Clauses," which provide that all new capital shall be offered either by sale or by public auction or by tender at a reserved price, to be sent under seal to the Board of Trade and after 28 days' previous notice, to be given to the Town Clerk of the City of London, the clerk of the London County Council and to the secretary of the London Stock Exchange, and after advertising the same four times during such period in two or more London daily papers (these conditions are supplemented in more recent Acts by provisions that the stock shall be issued at such rate of interest as in the opinion of the Governor of the Bank of England shall be best calculated to secure the issue of the stock at par), and further, that any premium derived from such issue shall not be considered profits of the company, but shall be expended in extending and improving their works and shall not be considered as part of the capital entitled to dividend.

The sinking fund clause has been inserted in special Acts of all the companies.

The first sinking fund clause was introduced at the instance of the City of London into the East London Company's Act of 1886. Since that time three other forms of the clause have been adopted in the case of the other companies, and now the clause has been applied to all the companies. Lord Llandaff's Commission which went carefully into the question reports that the operation of the clause in all cases is substantially this: "Whenever a company obtains power to borrow money on debenture stock the clause assumes that the money so borrowed earns profit at the average percentage of the dividend or interest paid on all capital of the company. The excess of that average percentage over the interest payable on the debenture stock *plus* 1 per cent. for management of such debenture stock is taken as the profit earned by the new money and the company are required to pay the whole of the excess to the Chamberlain of the City of London as trustee for the purpose of purchasing and holding shares of the company and of investing the dividends thereon with the view of ultimately extinguishing the capital of the company or for such other purpose as Parliament may from time to time determine." The effect of the clause is therefore to prevent any additional value accruing to the undertaking from the new loan capital.

III.—RECOMMENDATIONS AND SUGGESTIONS FOR FURTHER CONTROL.

The Balfour Commission 1892-93: The Balfour Report on the Available Supply of Water; Available Sources of the New River Company as given to the Balfour Commission, 1892; Available Sources of the New River Company as given to Sir Joseph Pease's Committee, 1896; The Balfour Commission on the Quality of the Water; The Balfour Commission Advise Control of Filtration; Information with regard to the Wells and to the Effects of Pumping required from companies.—Llandaff Commission: Terms of Reference; Intercommunication Scheme Advised and Passed; Water Board Recommended by the Llandaff Commission; Establishment of a Water Board Impracticable at Present; Purchase of Water Companies Opposed by Surrey; Water Board Undesirable for Kent; Control Recommended by the Balfour and Llandaff Commissions; Financial Control; Sir John Lubbock on "Internal Control" (Financial); The Anomalous Position of the Auditor appointed by the Local Government Board; Quality of the Water Supplied, Position of the Water Examiner; Suggestions as to Control made by the late Major-General Scott.—Conclusion.

THE BALFOUR COMMISSION, 1892-93.

The Royal Commission which was appointed to inquire into the water-supply of the metropolis in the year 1892 consisted of Baron Balfour of Burleigh, Sir George Barclay Bruce, Kt., Civil Engineer; Sir Archibald Geikie, Kt., Doctor of Laws, Professor of Geology and Mineralogy in the University of Edinburgh; Mr. James Dewar, M.A., Jacksonian Professor of Experimental Philosophy, Cambridge; George Henry Hall, Civil Engineer; James Mansergh, Civil Engineer; and Dr. William Ogle. The sittings of the Commission extended over a long period of time. The first meeting took place on May 16th, 1892, and the Commission sat at intervals until June 30th, 1893. The result of their sittings was that a quantity of matter was ultimately published consisting of the report,[5] a large book containing the minutes of evidence, a still larger volume containing the appendices to the minutes of evidence, another volume containing maps, plans, and diagrams, and an index published separately.

The matters which were investigated by the Commissioners and on which they reported may be conveniently divided into three parts. First, as to the quantity of water required for the supply of the metropolis; secondly, as to the quality of the water supplied at the time when the Commission sat; and, thirdly, as to whether any additional control over the companies' undertakings was advisable.

Anyone wishing to obtain an accurate account of the proceedings must read the report of the evidence and the book containing the appendices. The volume of the minutes consists of over 550 closely printed pages; the appendices contain over 690 pages. The report of the evidence and of the matter contained in the appendices are of greater value than the report of the Commissioners. Unfortunately some of the evidence given has been proved since to be inaccurate, and as the report was presumably founded on the evidence the opinion of the Commissioners in as far as it was founded on incorrect statements which they received as facts is valueless. It is, therefore, not necessary to deal at any very great length either with the evidence or with the report, but it will be necessary only to show clearly and briefly why it is that the prolonged labours of the Balfour Commissioners have, it must be feared, been to some extent wasted.

It will be best to take the subjects dealt with by the Commission under the divisions already given.

The Balfour Report on the Available Supply of Water.

As to the quantity of water which is available from the present sources, the evidence given before the Balfour Commission was not complete, because there are many districts within the area of Water London whose sources of supply and future requirements were not fully taken into consideration. This, however, is not a matter of very great moment.

The engineers of the metropolitan water companies gave evidence with regard to their sources of supply. It is not necessary to go into detail in the case of the sources of each company. It is sufficient for our purposes to show that the evidence given in one case has since proved to be wrong.

Available Sources of the New River Company as given to the Balfour Commission.

The case is that of the New River Company and it is necessary to go a little into detail with regard to the evidence given by the engineer of that company at the time of the Balfour Commission and the evidence which he has since given with regard to the amount of water which can be obtained from wells belonging to the company.

At the first sitting of Lord Balfour's Commission which was held on May 16th, 1892, Mr. Joseph Francis, engineer to the New River Company, was examined in regard to the amount of water which the company could supply. The evidence appears on pages 2 to 11 of the volume containing the minutes of evidence. A statement of the quantity of water which the New River Company had available is also given in the Appendix of the Royal Commission on the Metropolitan Water-supply, page 1. The statement in the Appendix is as follows:—

At this time the Company have available a quantity of nearly fifty seven million (57,000,000) gallons derivable from the following sources:—

	Gallons per day.
River Lee	22,500,000
Chadwell spring and wells	34,000,000
Ponds for non-domestic use, nearly	330,000
Daily	56,830,000

The next paragraph states: "This quantity is being continually augmented by further development and extension of the chalk well system." Mr. Francis was examined by Lord Balfour in regard to the details of the available quantity of water, and in answer to questions he said that the amount then used was 33,000,000 gallons daily. Of this 22,500,000 gallons came from the Lee the remaining 10,500,000 from Chadwell spring and wells. During the year 1891 the average amount derived from Chadwell spring was 2,000,000 gallons per day.[6] In answer to Lord Balfour the witness gave the quantities which he said the wells could produce daily should that amount be required. The table given was as follows:—

Broadmead Well	1,500,000	Turnford Well	3,250,000
Amwell End Well	1,500,000	Cheshunt Well	750,000
Amwell Hill Well	3,250,000	Hoe Lane Well	3,300,000
Amwell Marsh Well ...	2,800,000	Highfield Well	3,000,000
Rye Common Well ...	3,750,000	Campsbourne Well ...	3,300,000
Hoddesdon Well	2,160,000	Betstile Well (nearly)	500,000
Broxbourne Well	4,500,000		

In answer to Lord Balfour Mr. Francis said that they had never taken these quantities simultaneously from the wells. "We have," he added, "never needed to do so. I may say that these figures which I give by no means represent what we can get out of the wells by working the engines a little faster, but they are all worked at very moderate speed. We actually do get these quantities whenever we are working; but

[5] Report of the Royal Commission appointed to inquire into the Water-supply of the Metropolis. London: Eyre and Spottiswoode, 1893.

[6] It may be here noted that tables given to Lord Llandaff's Commission by Lord Robert Cecil on behalf of the Hertfordshire County Council showed that the flow of Chadwell spring has steadily and continuously diminished. During the summer of 1897 the spring entirely failed. The amount of water derived from wells was on the average 8,500,000 gallons less than the amount derived from the spring. Mr. Francis admitted that if the company obtained 34,000,000 gallons a day from the springs and wells that amount would be 23,500,000 more gallons than were obtained at the time the evidence was given. The basis of calculation on which the figure 34,000,000 gallons was arrived at was by taking what each well could produce, and had produced, over a period of weeks together, pumping day and night, taking each well separately, and then adding them together and finding the total amount. It was not the maximum quantity that could be taken from the wells, but a fair average of what could be obtained daily in a fair week's work from all the wells.

if we needed more water we could, by increasing the speed, get a great deal more out." In their report Lord Balfour's Commission accepted the figures given, that is to say, that the Chadwell spring and wells were capable of providing 34,000,000 gallons of water daily.

Available Sources of the New River Company as given to Sir Joseph Pease's Committee, 1896.

In the year 1896 a Committee was appointed by the House of Commons to report on Bills which were promoted by the London water companies. Amongst these Bills was one promoted by the New River Company and another Bill in which that company was interested—the Staines Reservoirs Bill. The Select Committee was composed of the following gentlemen:—Mr. Baldwin, Mr. Bond, Mr. John Brunner, and Mr. James Stuart, who were nominated by the House, and Mr. Brigg, Mr. Lewis Fry, Mr. Lees Knowles, Mr. Muntz, and Sir Joseph W. Pease, who were added by the Committee of Selection of the House. Sir Joseph Pease was appointed chairman.

On June 5th, 1896, Mr. Joseph Francis was examined at some length with regard to the amount of water supplied by the wells of the New River Company.[7] In answer to Mr. Balfour Browne he said that in the evidence which he had given before Lord Balfour's Commission he had stated that 56,830,000 gallons a day could be supplied by the company and that they would be able with new machinery to get a great deal more water. The witness would not admit that he represented to the Commission that 56,830,000 gallons were practically in hand, and he said that the Commission "fully understood" that it was nothing of the kind. Sir Joseph Pease said that although he did not desire to interrupt the examination he wished to remark that it was difficult to know what the Commission did understand except what they had put in their report, and that on page 27 of that report they had said that Chadwell spring and wells could supply 34,000,000 gallons daily, and he further pointed out that the witness in his evidence before them had put down the amount which could be furnished by Chadwell spring and the wells at 24,000,000 gallons daily which was 10,000,000 gallons less than he had estimated in the year 1892. The Chairman asked how it was that the figure had been put down at 34,000,000 gallons in 1892 and 24,000,000 gallons in 1896, and the witness replied, "Because we cannot rely upon the machinery always working. In the first place we must make allowance for unavoidable stoppages, for oiling heated bearings, and various causes. Then beyond that, out of the very great number of engines we have there are always some that have to be set off for repairs, and 10,000,000 gallons is not too much allowance to make for that." But Mr. Francis had told the Balfour Commission that 34,000,000 gallons was a fair daily average of what could be obtained, but that it was not the maximum quantity which they would be able to get should they require more.

This evidence speaks for itself. Comment is not necessary. It is seen from the figures quoted and from the evidence which he gave that according to the engineer of the New River Company the amount of water available for the use of the metropolis was found in the year 1896 to be much less in quantity from that which he stated was available when he gave evidence before the Balfour Commission. Lately before the Llandaff Commission it was asked if the engineer could in any way reconcile the figures which had been given before the Balfour Commission with those which he had subsequently given. The answer was that he had made a mistake.

It is quite evident that the conclusion with regard to the quantity of water available arrived at by Lord Balfour's Commission, based on erroneous data, are worthless and no more need be said on the matter.

Balfour Commission on the Quality of the Water.

With regard to the quality of the water-supply an enormous amount of evidence was given as to the sources of the water used by the metropolitan companies. Broadly speaking, the evidence may be divided into two sections. First, that given by the late Sir George Buchanan and by men who had made independent investigations into the matter; and, secondly, that given by experts employed by the metropolitan water companies.

A very interesting and instructive interview took place between Sir George Buchanan and the Commission at Trafalgar-place, Charing-cross, on Tuesday, May 10th, 1892. Anyone interested in the subject of water-supply, and especially of the importance to be attached to the source of the supply, would do well to read carefully the report of this interview. It is to be found on page 428 of the minutes of evidence of the Balfour Commission.

Sir Archibald Geikie towards the end of the interview asked Sir George Buchanan whether there was any particular line of research which he could suggest or recommend to the Commission in regard to the contamination of the sources of supply. Sir George Buchanan replied by recommending the Commission to go and look for themselves or to send someone else to look for them. "I do not think," he said, "there is anything but what I may call field observation, but go and see that what ought not to get into the water does not get into it."

Now, Lord Balfour's Commission did not adopt the method of "field observation." They did not apparently attach such serious importance as did Sir George Buchanan to the evidence given with regard to the pollution of the Thames and to the pollution of the Lee. They apparently attached more importance to the evidence of the scientific experts who were employed by the metropolitan water companies, and placed great reliance in artificial purification methods.

The Balfour Commission Advise Control of Filtration.

With regard to the control of the water companies the Commission recommended that greater power should be placed in the hands of the Water Examiner and that regulations should be made with regard to the filtration of water.

They attached the greatest importance to the efficient filtration of river water and they made important suggestions as to the control of filtration and to the method by which this control should be exercised. These recommendations are embodied in sections 176 and 177 of their report and are as follows:—

> We have further to consider what steps should be taken to ensure the proper treatment of the water that is taken from these rivers for the supply of London. For the water that flows down to the intakes must be subjected to certain important processes before it is brought into a suitable condition for delivery and consumption. These processes consist of subsidence and filtration, and the quality of the water when delivered depends largely upon the thoroughness with which they are carried out. It does not come within the terms of our reference to lay down what should be the exact regulations as regards filtration, that is to say, what should be the proportionate area of the filtering beds, the depth of sand, the frequency of renewal, or the rate at which the water should be allowed to percolate; nor, as regards the subsidence tanks how many days' storage should be deemed sufficient so as to obviate the necessity of taking in turbid storm water and to allow of due settlement; but we cannot shut our eyes to the fact that the provision for these purposes differs enormously in the different companies and in some of them is to our mind quite inadequate.
>
> Regulations on these matters should be drawn up after competent inquiry and adherence to these regulations should be strictly enforced. This enforcement should be entrusted to the public water examiner, who should have the legal right of entry into all the waterworks and the duty of reporting periodically as to the due observance of the conditions laid down. At present the examiner is only admitted to the works on sufferance and, though he has distinctly informed us that he has always been admitted not only without hesitation but with all courtesy by the various companies, it is plain that the standing ground of a man who is inspecting by right is very different from that of one who is only present by courtesy.

Information with regard to the Wells and to the Effects of Pumping required.

Another recommendation given in the Balfour report relates to the obligations which the Commission advised should be imposed on the companies to give accurate information in regard to the amount of water pumped from their wells and in regard to the height of the water in the wells. As we have already seen the information given by the engineer of the New River Company to the Balfour Commission in May, 1892, did not accord with that given by the same witness to Sir Joseph Pease's Committee in June, 1896. Now the Balfour Commission not only felt, but they also expressed, the difficulty they were labouring under in getting "accurate and reliable information," and for that very reason, amongst others, they made the following important recommendation:—

> We think it of very great importance that distinct obligations should be laid upon any company or local authority which is allowed to pump water from the chalk for purposes of public supply to keep accurate observation of the effect of their operations on the level of the water in the wells from which they pump, and return the results to the water examiner under such regulations as may be framed. The great difficulty which we have had to encounter has been in getting accurate and reliable information as to the actual effect of the operations now carried on. The importance of procuring this will increase each year as the limit of what can be taken from any district with safety is gradually being reached

[7] Report on London Water Companies' Bills, ordered by the House of Commons to be printed July 7th, 1896, p. 131, et seq.

The Balfour Commission looked forward to an improvement in the water-supply and suggested two things which appeared to have struck them as the most important factors in the consideration of the question. In the first place they recommended that the powers of the Thames Conservancy Board should be extended and that they should have jurisdiction over the tributary streams of the Thames. An Act passed in the year 1896 gave this power to the Thames Conservancy Board and very great improvements have resulted from its use by that firm and judicious authority. The other matter which appears chiefly to have struck the Balfour Commission was the importance of filtration, and they looked forward to the possibility that the Water Examiner, if and when he were placed in a position firmly to exercise his authority would be able by supervising the methods of filtration to ensure a great improvement in the quality of the water supplied by the companies.

THE LLANDAFF COMMISSION.

A Royal Commission to inquire into the water-supply within the limits of the metropolitan water companies was appointed on May 1st, 1897. The Commissioners were Viscount Llandaff, the Right Hon. John William Mellor, Sir John Dorington, Sir George Barclay Bruce, Mr. Alfred de Bock Porter, the late Major-General Alexander de Courcy Scott (the Water Examiner appointed by the Local Government Board), the late Mr. Henry William Cripps, Q.C., and Mr. Robert Lewis.

Terms of Reference.

The terms of reference were as follows:—

1. Whether having regard to financial considerations and to present and prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies it is desirable in the interests of the ratepayers and water consumers in those districts that the undertakings of the water companies should be acquired and managed either—(a) by one authority; or (b) by several authorities; and if so, what should be such authority or authorities. To what extent physical severance of the works and other property and sources of supply of the several companies, and the division thereof between different local authorities within the limits of supply, are practicable and desirable; and what are the legal powers necessary to give effect to any such arrangements.
2. If the undertakings are not so acquired, whether additional powers of control should be exercised by local or other authorities; and if so, what those powers should be.
3. Whether it is practicable to connect any two or more of the different systems of supply now administered by the eight metropolitan companies; and if so, by whom and in what proportion should the cost of connecting them be borne and what are the legal powers necessary to give effect to any such arrangement.

Intercommunication Scheme Advised. Act Passed.

During the sittings of the Commission it was decided to take all the necessary evidence on the third term of reference in view of a possible water famine in the East-end of London. The Commission issued a report advising that steps should at once be taken to allow intercommunication between the companies' mains, a Government Bill was brought in to carry out the recommendation, the Bill became an Act of Parliament, and measures were taken by the water companies to give a supply of water to the East London Waterworks Company.[8] The promptitude with which the measure passed was creditable, and the ready way in which both Houses of Parliament, in case of a pressing emergency, passed a measure which was undoubtedly for the public interest will, we trust, encourage the Government to deal without delay with the pressing needs of the people of London in regard to the water-supply. It is in that hope that we now proceed to deal with some of the recommendations given in the Llandaff report. The columns of THE LANCET have contained *résumés* of the evidence given before the Llandaff Commission. We cannot reproduce the reports of the evidence or the digests of the Llandaff report which have appeared in our columns. We can only give in the most brief outline the gist of that report, and point out why the Government cannot be expected to frame a measure to carry out all the recommendations it contains, and why, on the other hand, the Government would not be justified in simply allowing things to remain as they are, or, to be more precise, why they cannot be permitted to allow things to drift any longer.

Water Board Recommended by the Llandaff Commission.

The gist of the Llandaff report is to the effect that a Water Board should be appointed to buy the present water undertakings and to carry on the business of supplying London with water. It is also recommended that additional measures of control should be put into force and that this should be done in case either of the formation of a Water Board or in case the water undertakings are carried on by the companies.

It is necessary to say a few words about the Water Board proposed by the Llandaff Commission. The Board proposed would be a body elected by the London County Council, the Corporation of London, and the County Councils and Town Councils of the counties and towns which are situated in Water London—that is to say, the area at present supplied by the metropolitan water companies. The county of London would have no preponderating vote (or "voice"), although the rateable value and population of London would be greater than the rateable value and population of the extra-metropolitan districts. It is doubtful if the composition of the Water Board as proposed by the Llandaff Commission would satisfy anyone. Mr. Whitmore, Member of Parliament for Chelsea and a member of the London County Council, in the evidence which he gave before the Llandaff Commission said that no solution of the metropolitan water question would satisfy the "sentiment" of the London County Councillors if it did not give them a preponderating "voice." In an article which he lately wrote, however, Mr. Whitmore presses the Government to undertake immediate legislation with a view to carry out the recommendations of the Llandaff Commission. Now, as Mr. Whitmore is a "practical politician" it is necessary from our point of view to show why it is that the Government could not, without the most violent opposition, pass such a measure as that recommended by Mr. Whitmore in his more recent utterances.

Establishment of a Water Board Impracticable at Present.

"Water London," in the whole of which the proposed Board would reign supreme in all questions of water-supply, occupies an area of 620 square miles. The administrative county of London has an area of 121 square miles. But the districts outside London have interests which are not of less importance to them than the districts within London are to Londoners themselves. This proposition will be readily admitted, and it may appear at first sight hardly necessary to state it, but when the minutes of evidence of the Llandaff Commission are published it will be seen what an enormous amount of space is taken up by the evidence of the witnesses employed by the London County Council and by the London water companies, and what a small space is occupied by the evidence given by the representatives of the extra-metropolitan authorities. Now the weight of the evidence must not be judged by the weight of the paper necessary to report it. To take an example, the case presented by the county of Surrey may well serve.

Purchase of Water Companies opposed by Surrey.

The county of Surrey was represented by one gentleman, who appeared alone, without counsel, and gave his evidence very briefly. When the manner and method in which this evidence was given on behalf of Surrey is compared with the evidence given by the London County Council, represented occasionally by two learned counsel in addition to two or more officials whom doubtless the ratepayers pay, the contrast is rather striking, but the evidence of one country gentleman who devotes his time to the interest of his county and submits himself to a cross-examination by hostile counsel without any other protection than a sense of the justice of his cause deserves to be considered of no less value because the case is stated simply without words of supererogation, and therefore evidence of this kind is of no less importance than is that of scientific experts. The evidence of Mr. Halsey, the chairman of the Surrey County Council, was given at the twenty-seventh sitting of the Commission and is reported in the County Council Print, pages 1689–1712. It

[8] The only exception which could be taken to the measure had regard to the manner in which money was to be raised for carrying out the engineering work necessarily involved. The measure was necessary because had it not been passed it seemed probable that the East London Waterworks Company would be unable to supply its customers, and this being so it was not evident why the ordinary sinking fund clause should not have been introduced into the measure on its introduction into the House of Commons. A Committee of the House of Lords recommended that this clause should be introduced and the Bill was returned to the Commons containing it. The Commons, however, rejected the clause and the Bill afterwards became an Act without it. This is not the first occasion on which the House of Lords has interfered with a Bill from the Commons in a manner favourable to the London water consumers. In a Bill which was introduced in the year 1819 for limiting the charges of the metropolitan water companies a Committee of the House of Lords presided over by Lord Donoughmore advised that the water rents should be reduced to a lower level than that recommended by the Commons. The result was that as it was pretended that an alteration in the money clause by the Lords affected the privileges of the Commons the Bil was dropped.

is not necessary here to go into the details of the evidence, it will be sufficient to say that the Surrey County Council wished that the present arrangements for a water-supply to be given by the existing companies should not be interfered with. The evidence was concluded by a short sentence which was produced by the hostile examination by the Parliamentary agent to the London County Council. The final answer of Mr. Halsey, which apparently deterred the agent from following up the matter further and which, indeed, appeared to clinch it finally, was to the effect that purchase by any authority was undesirable and that purchase by the London County Council of the water companies' undertakings, as far as Surrey was concerned, was the worst possible basis of settlement which could be arrived at.

Water Board Undesirable for Kent.

The case of the county of Kent seems to merit quite a separate and special consideration. The history of its water-supply differs very much from that of any other district which came within the scope of the inquiry. The area supplied by the Kent Waterworks Company is a very large one, no less than 179 square miles. The business of the Kent Company has greatly extended as years have passed and the districts beyond those already supplied by the company have in several instances requested them to extend their area so as to include them also. There has been practically no conflict between the local authorities and the Kent Company.

Evidence with regard to the water-bearing strata of Kent was given before the Commission and there seems to be no doubt that there is enough water in the area to supply the county for many years to come. The question arose as to whether it was advisable for the Kent Company to join the other water companies in the scheme of intercommunication. The engineer to the company did not strongly urge that they would be benefited by it, and was evidently convinced that as far as their own area was concerned they could do perfectly well without any intercommunication with the mains of the other metropolitan water companies, for during the drought of the year 1898, when one of their wells failed and there was a breakdown of the machinery at another station, the company still had a sufficiency of water for their own wants. It was, therefore, impossible for the Kent Company to make out a strong case in favour of the hypothesis that the area which they supplied was likely to derive any benefit from any intercommunication with the mains of other companies.

A good deal of evidence was given before the Commission with regard to the amount of the percolation of rain-water which takes place in the chalk, but a scientific witness who was examined on the subject admitted that the amount of water which actually percolates is really a matter rather of speculation than of actual knowledge.

However, the evidence given by all the witnesses pointed to the conclusion that the area supplied by the Kent Company has within its own limits a perfectly adequate supply for the requirements of that district and for the supply of that part of the metropolis which is included in the statutory area of the company. It would be extremely disadvantageous to the people of Kent if their water were pumped away in quantity to supply London with water which the Kentish people require for themselves. The amount which is pumped at present is about half that which it is assumed could possibly be obtained. It is perhaps hardly necessary to point out that it is much easier to get the first half of the water than the second half.

A study of the situation of the wells of the company also shows that many of them are quite close to the boundary of the district—that is to say, the company has gone as far afield as they are authorised—for example, the new well at West Wickham is right on the border of the company's area; that at Shortlands is also close to it; the new well at South Fleet is not far from the western boundary of the company's district; and the well near the Pilgrim's Way south of the North Downs is, as a matter of fact, in the county of Surrey. There is no doubt, therefore, that the Kent Company's wells are so arranged as to take as much water as possible at places near their boundaries. What, it may be asked, does this mean? What importance has it? What has it to do with the question as to whether purchase by a Water Board or by some other body is expedient? And what has it to do with the question as to whether the water companies' undertakings should belong to one or to separate authorities?

Briefly this. Kent has a sufficient amount of water for her own needs. The populatiou is at the present time in many parts, however, sparse, but it is likely to increase. On the other hand, the amount of underground water will not increase. If the water-bearing area were to be under the control of any authority other than the County Council of Kent the interests of the people of Kent would undoubtedly be sacrificed to the wants of London. With regard to the question of a supply of water from Kent passing to a district outside their authorised area, one fact which was mentioned in evidence to the Llandaff Commission is not unworthy of note. The Kent Company supplied to the East London Waterworks Company during the year 1898 a certain amount of their water. It is not explained by what authority this was done. Now, although no one can possibly grudge the people of East London the small amount that the Kent Company was able to send during a period of famine, speaking from the point of view of the people of Kent it does seem that they have the right to know on what authority the Kent Company supplied water beyond their statutory area. In this particular case no harm was done to the people of Kent, but proceedings of that sort are liable to abuse, and if the water interests of Kent are not looked after by Kentish people the county will doubtless suffer in the future no less than Hertfordshire has suffered in the past, suffers now, and is likely to suffer in the future.

The people of Kent have been somewhat fortunate in having the matter of their water-supply managed by local men. Most, if not all, of the directors of the company are residents in Kent, and it is a good general sign of the satisfaction of the Kentish people as to the way in which their interests have been looked after that they should in more than one case elect as Member of Parliament one of the directors of their own water company.

In the course of the inquiry which was carried on before Lord Llandaff it was suggested that it might be advisable that the area now supplied by the Kent Company should be left intact. This would doubtless be the best solution for the people of Kent.

The question as to the rights in underground water was prominently brought before Lord Llandaff's Commission by Lord Robert Cecil on behalf of the county council of Hertfordshire.

We cannot, however, dwell on this question. It is quite certain that the people of Kent are not entirely forgetful of their own interests. Lord Llandaff's Commission showed that both the rural and the urban districts of Kent were aware of the danger which they would run should any authority other than a Kentish one have any power to abstract water from Kent and send it in quantity beyond their boundaries. A Parliamentary proposal to form a Water Board on the lines sketched by the Llandaff Commission would meet with the strongest opposition from Kent. Nor would any one of the metropolitan counties be content with such a measure. Enough we hope has been said to show that the Government would be extremely ill advised to bring in a Bill which would meet with general and merited opposition in the metropolitan counties.

Control Recommended by the Balfour and Llandaff Commissions.

Members of the present Government are responsible for the appointment of the last two Royal Commissions which were constituted to consider the question of the London water-supply. Both the Balfour and the Llandaff Commissions have recommended additional measures of control. And there are measures of control which should be supported by both political parties. They demand immediate attention. The things of greatest urgency may be best considered under the headings of (1) financial control; and (2) general control.

1.—Financial Control.

At the present time the financial control of the companies is in many respects satisfactory. In the first place the water rents charged are not generally excessive and they have been fixed by Acts of Parliament. The dividends which can be paid by the companies (except in the case of the New River Company) are limited by Acts of Parliament. New capital raised by the companies is allowed to be obtained only when provisions for a sinking fund are made.

Sir John Lubbock on Internal Control (Financial).

Sir John Lubbock, now a peer, in the evidence which he gave

before the Llandaff Commission brought forward, we think for the first time, some valuable suggestions as to the additional financial control which he considered fair to the companies and a matter of simple justice to the water consumers. Sir John Lubbock said that in his opinion control may be looked at from two points of view. There was external control, of which an example was that of the power now invested in the London County Council and in the Railway Commissioners by the Act which was passed in the year 1897. This Act, which has reference chiefly to the continuous system of supply, ought, he thought, to have a fair trial. To the other method of control Sir John Lubbock said he attached considerable importance. In his opinion control ought to be exercised over the financial arrangements of the companies. Some of them which are now paying a maximum dividend cannot pay any more to their shareholders however much more they may earn, and it has been alleged that there is *primâ facie* evidence that some of them are inclined to increase their expenditure, perhaps unnecessarily. Sir John Lubbock thought that it was important in any concern that those who were financially interested should have a voice in the management of the business in regard to such questions as to what salaries should be paid, as to the number of the *employés* engaged, and as to the amount of work which should be done by them. These matters could only be managed by what might be called "inside control"—they could not be determined by any exterior controlling body. As an example of such internal control Sir John Lubbock referred to the case of Indian railways in which the Government has a large interest. In the case of these railways, he said, the Indian Government appointed one or more directors to look after their interests in the management of the railway. He thought that the case of the metropolitan water companies was somewhat analogous.[5] The people who paid water-rates in London were practically in the position of ordinary shareholders; for example, in the case of the customers of the West Middlesex Company those people who hold the ordinary shares are practically at the present time preference shareholders. They are entitled to a fixed dividend which they are receiving and they are not entitled to anything beyond this. The persons who really stand in the position of ordinary shareholders are the water-rent payers because they are actually the people who benefit by improved management and by increased profits. For at the present time now that the full dividend is being paid to the shareholders anything which remains over must necessarily be applied to reducing the price charged for water. It is therefore only reasonable that the water-rent payer should be allowed, either through local bodies or in some other way, to appoint representatives to the board of the company to see that their interests are properly looked after. Sir John Lubbock, in giving his evidence, said that he did not wish to suggest that the interests of the water-rent payers were not at the present time thoroughly looked after, but he strongly held that as a general rule and as a matter of principle those people who have a substantial financial interest in the success of a company ought to have a voice in the management of the concern, and it was from that point of view and because the water-rent payers had a direct interest in some of the water companies' earning powers and a contingent interest in others that it was only fair and right that they should have one or more directors on the board of managers. He thought, moreover, that the system would work well. There would be no conflict of interest between the company and the water-rent payers in these matters. Sir John Lubbock said he had not thoroughly considered the questions as to how and by whom the new directors should be elected. In the case of Kent, however, he thought it would be best that the nomination of them should be made by the Kent County Council or by the urban authorities, because if this were done they would get men who really understood the matter. He did not think that it would be well for the London County Council to elect the members because, as everyone knew, the election of members to that body depended on considerations which had no reference to the management of water undertakings. On the other hand, if members were appointed by a local authority those who had had previous experience of such undertakings would doubtless be elected.

With regard to the way in which the new directors would work with the old ones Sir John Lubbock said that his experience of boards was that they were very reasonable and that it very seldom happened that there was any division on the board. The advice of those most competent to judge was usually taken and there was no reason if his proposition were carried out why there should be any conflict of interest. His impression was therefore that things would work smoothly.

The Anomalous Position of the Auditor appointed by the Local Government Board.

There is another matter with regard to control which appears to be most unsatisfactory. The auditor of the accounts of the metropolitan water companies who is appointed by the Local Government Board is paid by the water companies and no provision is made for the payment for any legal advice which he may require in dealing with the accounts of the companies. Mr. Alan Stoneham, the gentleman appointed by the Local Government Board, gave a full account of his duties and of the way in which he carried them out at the thirtieth sitting of the Llandaff Commission. By the provisions of the Act of 1871, under which he was appointed, it was enacted that the auditor was limited with regard to the number of back years for which he was allowed to examine the capital accounts of the companies; that is to say, he could only examine the accounts back to a certain date in the case of each company. The dates in different cases varied from the years 1864 to 1869. Mr. Stoneham audited the accounts which were available in each case and ascertained the method in which they were kept. He had first to satisfy himself that the accounts were kept on a proper system. He had perforce to assume that the existing capital as stated in the accounts of each company was the correct amount of capital. But from the date at which he began his duties he was empowered to allow such sums only to be placed to capital account as in his opinion might properly be so placed. Lord Llandaff asked the witness what would happen when fresh capital was raised if the auditor suggested that some of the amount which the company proposed to spend could not properly be considered capital expenditure. Mr. Stoneham replied that he would not allow any sums which ought not to be credited to capital account to be put there. He looked upon it as a conversion of so much gold in the till into engines or pipes or whatever the money was spent on. Lord Llandaff pointed out that if that were so it was the conversion of a permanent asset into a perishable one and he inquired of Mr. Stoneham as to whether account was taken of the deterioration or depreciation of the plant. Mr. Stoneham said that there was no depreciation account and nothing was "written off" from the capital account for deterioration and depreciation. With regard to the machinery he said that if an engine wore out it was replaced and the charge was put against the revenue of the company, and he accepted the statement of the engineer that the new engine had been put to replace the old one. He did not assure himself with his own eyes that the engine had been replaced by another and proper engine. Mr. Stoneham said that he was not aware that before the water famine which occurred in the year 1894–95 a number of pipes were likely to burst. But the pipes did burst and the accounts of the outlay necessary for reinstatement were taken to him. The matter of how the pipes were to be paid for was discussed by him with the representatives of the companies. It was decided that a certain amount of the expenditure might fairly be charged to capital account and some to revenue. The reason why some part was charged to capital was that the pipes were placed at a greater depth below the surface of the ground than the pipes which they replaced. Mr. Stoneham thought that a certain proportion of the outlay might be reasonably considered to be new work and he had therefore allowed a certain proportion of the expenses incurred to be charged against capital because the pipes had been so lowered.

During his term of office a somewhat curious arbitration case had arisen between the New River Company and himself. It arose in this way. The New River Company had some land at Blackfriars which they sold at a price higher than that which they originally gave for it. The New River Company had contended that the profit should go to revenue and that it should be paid to the shareholders. On the other hand, the auditor contended that the sum so received should be written off the capital. The matter came before the Lord Chancellor who held that the appreciation of the value ought to be considered and treated as revenue. A member of the Commission (Mr. de Bock Porter) asked

[5] In the case of the Indian railways the Government representative has, we believe, much more power of control than Sir John Lubbock suggests should be exercised on the metropolitan water companies.

Mr. Stoneham whether he did not admit that in some cases, in which part of the plant and works of a company had been disused, they became of less value, and Mr. Stoneham replied that he had no official knowledge on that subject. On being further asked who had such a knowledge Mr. Stoneham pointed out that that was a question which did not appear in the accounts of the company, and that he only looked at the accounts which had been made up since the date of his appointment. The Local Government Board had not laid down any instructions for his guidance. If he misconducted himself the Board had the right to remove him, but otherwise they had no right to interfere with the way in which he carried out his duties.

With regard to the question of accounts of money paid in Parliamentary expenses, and as to whether it was debited to the capital account of the company, or whether it was paid out of revenue, Mr. Stoneham explained that before a Bill brought forward by a company became an Act the expenses were paid from the income of the company and in the case of a company opposing Bills all the expenses were paid from the income of the company. He could give no idea as to the amount which the companies had spent in opposing the Bills brought in by the London County Council. He carefully abstained from anything like interference. It may, perhaps, be worth while at this point to remark parenthetically that should a Bill be brought in by the West Middlesex Company and opposed by the London County Council (or *vice versâ*) the whole of the legal and Parliamentary expenses are paid by the London ratepayers and by the water consumers who live in the area supplied by the West Middlesex Company.

With regard to office expenses Mr. Stoneham said that he had the assistance of clerks, but should a dispute arise no provision was made by which he could obtain counsel's opinion, and he had himself borne this expense, paying the money out of his own pocket. In one case which came before Sir Henry James [9] as arbitrator the late Solicitor-General and Mr. Justice Wright were against him. Sir Henry James took the case and argued it so as to give the auditor as much help as possible. He said: "Mr. Stoneham is not represented by counsel and you will understand I will argue it for him." Lord Llandaff inquired whether the auditor meant that Sir Henry James argued to Sir Henry James on account of Mr. Stoneham, and the reply was that he, in fact, did argue the case to himself, appealing to Mr. Stoneham from time to time. Mr. Stoneham said that he found himself at a very great disadvantage in the case (a statement hardly complimentary to Sir Henry James) and therefore in the next case which occurred, when he appeared before Sir Robert Reed, counsel represented him and he paid the fees himself. Lord Llandaff asked whether when the auditor had a difficulty in discharging his duties and the matter had to go to arbitration there was any provision by Parliament that his expenses should be met out of some fund, and the auditor replied that there was no such provision. Lord Llandaff suggested that it was a very serious blot on the Act and the witness concurred that it was a very serious blot. He said that he had never applied to the Board of Trade for legal costs and the water companies had to pay for "taking up the case" (i.e., paying the arbitrator's fees).

It does seem most curious that an auditor appointed under an Act of Parliament by a public department should be in the position in which the auditor of the accounts of the metropolitan water companies showed that he was placed. Such an important officer ought surely to be provided with any legal help which he wants. Is it not a most monstrous state of things that a Parliamentary official acting on behalf of the public should be placed at such a disadvantage? Is it not certain that the interests of water consumers must necessarily suffer? However able and painstaking the auditor may be, is it likely that he has sufficient knowledge of legal technicalities to be able to hold his own against the most clever and skilled counsel who can be employed by the water companies? And to put the matter on higher ground, is it a dignified proceeding that a Parliamentary official should have to contend single-handed against counsel employed by rich trading companies? Surely this state of things should be altered without delay.

The report of the Llandaff Commission recommends that provision should be made for the auditor to have counsel's advice paid for by the Local Government Board. We are strongly of opinion that the auditor himself should also receive a liberal salary and that the money to provide it should not be paid by the trading companies whose financial peculiarities it is his duty to check in the public interest.

Quality of the Water Supplied: Position of the Water Examiner.

With respect to the control now exercised as to the quality of the water the Metropolitan Water Act of 1852 (as we have seen, p. 187) provided that no company should resort to any new source of supply without the permission of the Board of Trade.[10] The control with regard to the source of supply appears therefore to be adequate. Certain powers are also exercised under the Acts of 1852 and 1871 with regard to ensuring that water of good quality should be supplied (see p. 188). Under the latter Act the appointment of a Water Examiner by the Local Government Board caused a great improvement in the matter of control, but the provisions made as to the powers and payment of that officer need amendment.

At the present time the Water Examiner has no power of entry on to the premises of any metropolitan water company. This matter was referred to in the report of the Royal Commission presided over by Lord Balfour, and in their report the Commissioners recommended that power of entry to the company's works should be given to the Water Examiner and that he should therefore be able, as a matter of right, to enter any of the premises of the metropolitan water companies instead of visiting them as he now does on sufferance and as a matter of courtesy. Many witnesses who gave evidence to Lord Llandaff's Commission referred to this matter and no representative of any of the water companies made any objection whatever to the proposed alteration. Indeed, one witness who appeared on behalf of the water companies suggested that in his opinion the water analyst or any other person appointed by the Water Examiner for the Local Government Board might well receive the right at any time to make any investigation which he thought fit with regard to the manner in which the water companies carry on their business.

The question as to the remuneration of the Water Examiner is one which cannot be passed over without a few words. At present, as we have seen (see p. 188), under the regulations of the Act of 1871 the Water Examiner appointed by the Local Government Board is paid by the metropolitan water companies. It is not right that the water companies should be called upon to pay an officer of the Local Government Board. It is not suggested that there is really any want of dignity in the reception by the gentleman who holds the appointment of Water Examiner of money which is paid by the water companies. The payment is of course made through the Local Government Board, but it is not seemly that an officer of such importance, whose duties are so responsible, should be paid, either directly or indirectly, by a number of trading companies whose businesses he has to overlook in the public interest. The Water Examiner to the Local Government Board is in all respects a public official and he should be paid from public funds. It is neither right nor dignified for a public department to allow it to be truthfully said that one of their officers is paid out of the profits of private businesses. Now the representatives of the metropolitan water companies do say that they pay the Water Examiner, and it is true that they do. They do so because they are required to do so by a statutory enactment. This may possibly by some people be considered a trivial matter, but we maintain that it is not a trivial matter. The amount of payment which the Water Examiner receives is doubtless totally inadequate payment for the duties which he performs. Such an officer should be highly paid and should have at his command a sufficient and efficient staff. The information which he publishes for the public should be his own information and the information of his own officers. At the present time this is not the case. The monthly report of the Water Examiner contains a number of statements with regard to the quantity of the water-supply and details are given as to the quantity derived from the Thames, from the Lee, and from wells. These figures are supplied by the water companies' servants. The Water Examiner has no power to check them; they are published in an official report and then the figures become official and the "official figures" given by the Water

[9] Lord James of Hereford.

[10] This power is now vested in the Local Government Board.

Examiner are quoted as such by the representatives of the water companies. Major-General Scott, the late Water Examiner, pointed this out to his fellow members of Lord Llandaff's Commission. There is no secret about it. It is a matter which certainly ought to be altered.

These statistics are not the only things which are supplied by the companies to the Water Examiner. Every month he reports on the quality of the water supplied by the companies. Some of these reports are made by scientific experts who are employed by the companies and they are then published in the official monthly bulletin of the Water Examiner.

With regard to the quantity of water supplied to London, we have already quoted an important recommendation made in the report of Lord Balfour's Commission (see p. 191). We entirely agree with the suggestion that a distinct obligation should be laid upon any company or local authority which pumps water from the chalk for purposes of public supply to keep accurate observation of the effect of these operations on the level of the water in the wells from which they pump and return the results to the Water Examiner under such regulations as may be framed. The great difficulty which the Balfour Commission had to encounter, the report says, had been in getting accurate and reliable information as to the actual effect of the operations now carried on. The importance of procuring this will, as they say, increase each year as the limit of the amount which can be taken from any district with safety is gradually being reached. Now, this suggestion that accurate observations on the water level and the wells of the metropolitan companies should be given to the Water Examiner has not yet become a statutory obligation. The date of the report of Lord Balfour's Commission it may be remembered was 1893, and since that time nothing whatever has been done to carry out this important recommendation. Had it been carried out Lord Llandaff's Commission would have been in a position to see what changes, if any, had taken place in the water level of the wells belonging to the New River and to the Kent companies. At one of their sittings the Llandaff Commission decided that they would not "go behind" the evidence of Lord Balfour's Commission with regard to the quantity of water which could be obtained in the valley of the Thames and of the Lee. Lord Llandaff's Commission, in short, decided not to re-open this question. It is certain that changes have taken place and new conditions have arisen since the date of the Balfour inquiry.

At the Llandaff inquiry Mr. Bowles Bowles, chairman of the New River Company, absolutely declined to give information to Lord Llandaff's Commission with regard to the levels of the wells, and Mr. Francis, chief engineer to the company, objected to give such information because, he urged, the facts would be misleading. Lord Robert Cecil, who appeared before the Llandaff Commission on behalf of the Hertfordshire County Council, and in defence of the rights or alleged rights of the rural water consumers of that county, gave Mr. Bowles Bowles and Mr. Francis every opportunity of affording information, but they evidently had no wish to supply facts which would necessarily have been universally known had the recommendation of Lord Balfour's report been carried into effect by giving it the force of a statutory obligation. Now the study of the tables giving the flow of the New River Company's Chadwell Spring gives support to the general theory propounded by Lord Robert Cecil that the water levels of chalk in Hertfordshire are, and have been for years, gradually sinking.[11] Lord Llandaff pointed out to Lord Robert Cecil that the inquiry on which he was engaged did not embrace consideration of the depletion of the chalk of Hertfordshire. We must, however, suggest, and indeed insist as strongly as possible, that it is of great importance to the people of Hertfordshire, and it is of great importance to the people of Kent, to know accurately the state of the underground water in their respective counties. The measure of control which was recommended in Lord Balfour's report is a measure which Lord Llandaff's Commission have advised Parliament to carry out without further delay. The evidence which has been given by witnesses from the county of Hertfordshire, evidence which will be found in the notes of the report of the Llandaff Commission when they are published, conclusively proves that the people of Hertfordshire have suffered greatly from the depletion of their wells. The facts given have not been contradicted. The same thing may in the future possibly happen in Kent, but if the people of Kent are able to keep for themselves the water which is found "under their feet" they will have less reason to complain. Still in the case of Kent some of the representatives of local authorities have expressed the regret which they now feel that they have allowed the control of the water-supply to pass out of their own hands into that of a commercial company, and if any large amount of water were taken from Kent and sent to the metropolitan area it might well happen that a very inadequate supply would be left to the people of Kent, and it would become a very serious matter for them.

One of the directors of the Kent Company admitted that in any case of inadequacy of supply the fullest information should be given to the public with regard to their wells; but neither he nor the engineer to the company were willing to give to the Llandaff Commission all the information which they possessed as to the height of the water level in the wells. Now if the recommendation of Lord Balfour's report had been made a statutory necessity and a record had been kept of the amount of water pumped daily from each well and a record had been kept of the level of the water in each well daily, and if this information had been regularly published the people of Kent would be in a position to know from week to week or from month to month the state of the underground water in their county. We must insist that it is of the very greatest importance for the people of Kent that this should be done in the future and that a beginning should be made without delay. The County Council of Kent should know as much about the water-supply of their county as possible. From the point of view of the public it is not satisfactory to know that things which were of great moment to the water consumers and which were recommended in the Balfour report have never been carried out.

Suggestions for Control made by the late Major-General Scott.

With regard to the question of control of the metropolitan water companies Major-General Scott made some valuable suggestions in the course of his examination of some of the witnesses who appeared before Lord Llandaff's Commission. The suggestions were conveyed in the form of questions which he addressed to the witnesses. In his examination of Mr. Whitmore Major-General Scott asked the following question: "As regards control should not you consider that the supervising authority should acquaint itself with the state of the works thoroughly and continuously, as it were; that its supervision should be directed to see that every company maintains its works in a proper state of efficiency; and that it should look to the future efficiency from the point of view of starting works in a reasonable time so that there should be no failure from want of capacity in the water-supply? Would not you think that that kind of control would do good? There is no such control at present." Now, as we have seen, the West Middlesex Company pay their full dividend. The shareholders of the company cannot receive more than they do at present. Any money earned in excess of the amount necessary to pay dividends has either to be employed in the working of the business or paid back to the water renters in the form of a reduction in their rates. The West Middlesex Company have had a successful business for a considerable number of years and have not only kept their plant in a state of efficiency but have looked ahead and made provision for the development of future business. This course of conduct has not been adopted by all the metropolitan water companies. In the case, for example, of the Southwark and Vauxhall Company the amount of water abstracted from the Thames was for some time greatly in excess of the amount authorised by Parliament, and sufficient provision was not made for the treatment by sedimentation and filtration of the increased amount of water so taken. The Southwark and Vauxhall Company were not financialy in as flourishing a position as the West Middlesex Company. These are facts it is well to keep in mind because they have a direct bearing on the question asked by Major-General Scott, and which has just been quoted.

Another question which contains a valuable suggestion was the following: "Assuming that a company is in rather bad circumstances and that the directors

[11] The engineer to the New River Company suggested that Chadwell Spring had failed because there was a "crack in the basin." Later in the course of his examination he said that he thought that there was a 'crack in the basin" because the spring had failed.

do not like to face the shareholders from time to time with their diminishing dividends, then it is rather an inducement under those circumstances to postpone the construction of works that anyone who looks to the future must see would be absolutely necessary. As these works take as much as five or six years to construct, if they (the directors) postpone the work too long they will find themselves at the end of that time in this condition—that after a dry season (a season of drought or something of that sort) the supply fails and it is absolutely out of the power of anyone to remedy the defect, and then the people complain; but it is too late to complain, no remedy can be applied which would not take months or years to carry out, and therefore the thing is irretrievable. Would it not be a wiser kind of administration which would overlook the company in such a way as to be able to say to a company, 'The time has arrived when you should start certain works or you will find yourselves in a mess.' Would it not be better if such an authority should put for the public a pressure on such a company to oblige them to start the works. Would it not, I say, be a wiser system of administration than to wait until complaints arise of scarcity in a district and an enormous amount of privation occurs, a state in which it is impossible to remedy things?"

Here is another valuable suggestion. "If you look at the Acts of Parliament of 1852, 1871, &c., you will see that the idea of control of some sort or other pervades the whole of them, or a great portion of them. That control really amounts to this, that when anything goes wrong somebody is to be punished, but would it not be better to prevent the wrong originally so that the complaint of wrong-doing should not arise?"

These suggestions deserve the most careful consideration. It may be doubted if they could be carried into effect with the entire approval of those Members of Parliament who are also directors of water companies and who are often listened to in the House as "practical men" with a thorough working knowledge of all matters pertaining to water-supply. But Major-General Scott's questions were asked in the interest of water consumers who were not represented by counsel and the questions were based on a thorough and long experience of all the details of the metropolitan water-supply.

CONCLUSION.

The matters of greatest urgency in respect to control of the London water companies are:—

The auditor appointed by the Local Government Board should be in all respects an officer of that Board and his salary should be paid from public sources. He should, when he wishes it, in the case of any difference with the water companies have the advice and help of the law officers of the Crown.

The Water Examiner appointed by the Local Government Board should have access to all parts of the metropolitan water companies' undertakings. He should be entirely responsible for the report which he issues monthly. The companies should be obliged to place at his disposal every facility for making the several investigations which he wishes. Every investigation which the Water Examiner makes should be done either by himself or by officers appointed by him. Any analyst he may employ should be nominated by himself and all the necessary expenses entailed in carrying out the work necessary for him to give full and accurate information should be paid by the Government department.

No Member of Parliament who represents any part of Water London, whatever may be his political conviction, could fairly object to the measures of control which we have just indicated. The Government having appointed and received the reports of two Royal Commissions have no right to make any further delay, and as both the Balfour and Llandaff Commissions have distinctly reported in favour of increasing the power of the Water Examiner they have no legitimate reason for delay in passing a simple measure which will carry out this recommendation. Any Member of a metropolitan constituency who, either from indifference or because he is a director of a water company or from any other reason, failed to support the Government in passing a measure for the benefit of the whole of the water consumers would richly deserve to lose his seat at the next election. It is now some years ago that the Right Hon. A. J. Balfour said he would not have London water-supply considered as an Imperial question. It is not an Imperial question, but it is of great importance to the people of London and it ought not to be treated as a party question.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund up to July 18th, when the total exceeded £45,000:—

	£	s.	d.
St. Jude's, South Kensington	655	0	0
St. Matthew's, Bayswater	142	0	0
St. Bartholomew's, Sydenham	106	0	0
St. John's, Paddington	165	0	0
St. Paul's, Knightsbridge	268	0	0
Holy Trinity, Tulse-hill	171	0	0
St. Margaret's, Westminster	107	0	0
Portman Chapel, Baker-street	121	0	0
Holy Trinity, with St. Jude, Upper Chelsea	296	0	0
St. Peter's, Kensington-park-road	128	0	0
Parish of St. Peter's, Eaton-square: Parish Church, £542; St. John's, Wilton-road, £67; St. Peter's Chapel, £6; total	615	0	0
St. Peter's, Cranley-gardens	400	0	0
St. Michael's, Paddington	144	0	0
St. Stephen's, Gloucester-road	103	0	0
St. Michael and All Angels', Southfields	25	0	0
Holy Trinity, Islington	24	0	0
Ilford Parish Church and Chapel	33	0	0
St. Barnabas', Pimlico	32	0	0
St. Paul's, Greenwich	20	0	0
All Saints', Clapham-park	36	0	0
St. John the Evangelist, Upper Holloway	24	0	0
St. Mary's Parish Church, Wimbledon	51	0	0
St. John's, Wimbledon, and Missions	54	0	0
Heath-street Baptist Chapel, Hampstead	56	0	0
Essex Unitarian Church, Kensington	95	0	0
Christ Church, Forest Hill	54	0	0
St. Mary Magdalene, Paddington	32	0	0
St. John the Evangelist, Penge	96	0	0
St. George's Presbyterian Church, Brondesbury	20	0	0
Church of Ascension, Balham-hill	51	0	0
St. Mark's Presbyterian Church, Greenwich	33	0	0
St. Paul's, Harringay	28	0	0
Highbury-quadrant Congregational Church	65	0	0
Greek Church, Bayswater	72	0	0
Highbury Presbyterian Church	26	0	0
St. John the Divine, Kennington	51	0	0
St. Luke's, Redcliffe-square	90	0	0
St. Matthew's, Sydenham	26	0	0
Trinity Presbyterian Church, Notting Hill	29	0	0
Catholic Apostolic Church, Maida Hill West	25	0	0
Camden Church, Camberwell	44	0	0
Lyndhurst-road Church, Hampstead	75	0	0
St. Mildred's, Lee	32	0	0
St. Peter's, Streatham	45	0	0
St. Anne's, Soho	56	0	0
St. Andrew's, Wells-street	71	0	0

THE LANCET.

LONDON: SATURDAY, JULY 21, 1900.

WE have the highest of all authorities for believing that "Wisdom is justified of her children." The truth of the statement must occur to the minds of most of those who read, or were able to hear, the Croonian Lectures which Dr. F. W. MOTT has recently delivered before the Royal College of Physicians of London. They are for the most part the product of the far-seeing wisdom of the London County Council in establishing a laboratory with adequate means for the investigation of the minute pathology of the diseases under treatment at their asylum. It is also an illustration, although not the first, of the wisdom exercised in the selection of a superintendent, whose diligent use of the few years in which he has been at work and his utilisation of the material which has come under his disposal are conspicuously shown in these lectures. We find, indeed, throughout them abundant traces of the work which made Dr. MOTT'S name familiar before his appointment and which furnished the ground on which his appointment was made, but the chief part of their substance consists of the results of researches undertaken by him, or under his direction, at the County Council's Pathological Institute at Claybury; and the extent of this, its value, as well as the manner in which it is presented, must excite the admiration of all those who are capable of estimating its worth.

Originality is the key-note of the presentation which is here given to us of the pathology of nervous disease. All that is presented with this freshness is not indeed new. Many as are the references to the work of others, such a description of the facts, even in the light of original research, must traverse the results previously obtained at more points than it has been possible to indicate. But this does not diminish the interest of the account or its value to all those who are at work on the same subject, and indeed to all those who care to give to the lectures the careful perusal which they require if they are to be perfectly understood. The subject does not lend itself to simple statement. The rapid advance of neurology has brought into almost colloquial use among experts many terms which are still unfamiliar to the majority and the amount of fact with which the lecturer has had to deal has compelled a condensed style which certainly needs close attention to understand. But the requisite attention will be forthcoming from the readers to whom the lectures specially appeal.

The title of Dr. MOTT'S lectures is alike accurate and misleading. The transformation of our conceptions of the nervous system involved in the doctrine of the "neuron" is vaster than is commonly conceived and its wide extent is illustrated in the subjects considered in these lectures. It will be noticed that a final "e" is attached to the word. "Neurone" is the French term, but in all other countries, and generally in this country, the word "neuron" is employed. The addition of the "e" is apparently due to the persistence of Professor SCHÄFER in applying the word "neuron" to the axis-cylinder process, commonly termed the "axon," in opposition to the general use of the word. Dr. MOTT'S modification of the term is harmless, but we doubt whether it will be effective to prevent confusion, or is really required. The vitality of words is often insusceptible of control, even as regards their form. The fittest survives, in contempt of etymology.

Even those who have some acquaintance with neurology might conceive that the title "degeneration of the neurone" would cover a limited region of the minute pathology of the nervous system. The perusal of these lectures will reveal to many for the first time the extent of the change in our conceptions which is involved in the new doctrine. The neuron is now perceived to be the universal unit of the nervous system, the element of its constitution in all parts, so that the "degeneration of the neurone" becomes conterminous with all the processes of degeneration in the nervous system. Not only does the lecturer frankly employ this wide conception, but he includes under the term "degeneration" the changes which are produced by acute processes as well as those which constitute the chronic changes to which the word is often restricted. He is thus able to stretch his net so widely as to gather in it most of the maladies which are not the result of obvious external inflammation. The subject is thus a very large one, and the variety of diseases which it includes is such as to permit, in respect to many, only a glance at those features which have a relation to the special subject.

It is at first somewhat startling to remember that the doctrine of the neuron is one which is still without actual proof. It is essentially founded on the discontinuity of the nerve elements which proceed from each single nerve cell. They were formerly thought to unite at their extremities, their nutrition being still believed to depend on their connexion with the cell. The union of the divided terminations of the branches is now doubted by most histologists. They are believed to be only contiguous, and that the excitation of the adjacent fibrils is effected by a process of stimulation and not continuous conduction. The belief that there is discontinuity rests on the fact that union cannot be traced. But the conditions of observation are such as to leave some investigators still in doubt regarding the validity of the general inference, although the evidence has been accepted so generally that pathologists have no choice but to follow the lead presented to them. The result affords an explanation of so much that was before obscure in pathology as to constitute strong evidence of the truth of the doctrine. This evidence is presented to us by Dr. MOTT with great force and for the most part with effective cogency. But he recognises that, though discontinuity is probable, the union asserted by some does not lessen the general significance of the "neuron" conception of distinct nutritional units. While he regards separation of the elemental parts of the nervous system as probable, he considers that it is not essential to the neuron-conception. He believes that the terminal branches of the processes may be sometimes separate and sometimes continuous. Some hesitation

may be felt in following him here. It is not likely that both systems obtain in the nerve-centres. On either view we can understand that secondary degeneration does not pass into the nutritional domain of another cell. But continuity involves simple conduction; discontinuity implies re-excitation. A new nerve-impulse is excited by the stimulus of that which reaches the adjacent termination of the neuron which conducts the afferent impulse, and the enormous augmentation which occurs in many central processes, as in reflex action, seems more readily thus explained. It is doubtful if we can assume the existence of the double relation or the occurrence of the double process.

As an illustration of the fact that at the present time research is only laying the foundations on which the future superstructure of knowledge must be built may be mentioned the discrepancy in the results obtained by staining the nerve-cells in artificial cerebral anæmia. In the parts of the brain thus deprived of blood considerable alterations are seen in the cells and their processes when these are stained by the Nissl and other methods, but when treated by the chrome-silver method of Golgi both appear perfectly normal, including the gemmæ on the branches. Dr. MOTT draws the inference that only a few of the cells are stained by Golgi's method, and that a large number escape perception altogether in spite of the perfect staining of those which respond to the agents. Considering that it is by this method that the absence of union between branches has been discerned, that it is on the results obtained by this method that the doctrine of separate neuron-units entirely rests, the statement, if true, seems to throw a good deal of reputed fact back into the crucible. We have here an instance of the mental reservation which must be given to many of the conclusions which are put forward as established facts, but which only merit at present provisional acceptance.

The development of the elements of the central nervous system is a subject of which Dr. MOTT has given a full sketch in his introductory lecture. It may at first sight seem anomalous that development forms part of a study of degeneration. But the reason is obvious, and the only objection that can be taken is to the narrowness of the title given to that which has so wide a scope. Development and decay are processes of opposite nature. They underlie the progress and cessation of the vitality of the tissues. The one attends the development of functional capacity, the other its failure. Dr. MOTT has given useful descriptions and illustrations of the remarkable results of the investigations of FLECHSIG, BECHTEREW, and others, which have established the differences in time at which the fibres of the central nervous system acquire their full structural development by the formation of the myelin sheath. The relative time at which this takes place corresponds with the order in which the functions are acquired that the structures subserve. The afferent fibres to the brain develop before those that conduct voluntary impulses, and among the earliest to achieve the myelination necessary for function are those which conduct impulses from the skin, joints, and muscles of the fœtus, whose movements must continually generate afferent impulses through the fibres. The researches of HELD have shown that function exerts a marked influence on this process of myelination. If one eye is kept closed the fibres from it develop perfect structure later than those from the eye which is open, but this is not the case if the animal is kept in the dark. There is, however, a tendency to ordered myelination independent of function. The latter has only a modifying influence, but it can clearly accelerate or retard the process.

It is not practicable to epitomise Dr. MOTT'S condensed sketch of what has been ascertained regarding the histogenesis of the sheath of Schwann, and the conclusions at present reached in regard to the development of other structures are not yet of clear significance. The special subject of the lectures, the degeneration of the neuron and its varied relationships, must be reserved for notice in another article.

SEVERAL of the larger and smaller towns in this country have now come to be known, by their mortality and notification returns, to suffer to an exceptional degree from enteric fever in endemic form. In many of these places it has been found impossible to connect causally the continued prevalence of enteric fever with any of the agencies of infection to which pronounced epidemics of typhoid fever are commonly due. Specific pollution of drinking-water, milk, shellfish, ice-cream, and the like may indeed now and then have caused an increase of the customary amount of enteric fever; perhaps a particular period of sustained fever prevalence has seemed to have been started by an outbreak which was traceable to infected food or drink; but the appearance of enteric fever year after year in excessive amount has quite certainly not been occasioned by recurring exposure to infection through such agencies. Recently much attention has been given to the part which may be played by polluted soil in the transmission of enteric fever infection, and it becomes important to consider soil in this connexion. In individual instances the ability to carry infection of soil, using the word in the narrow sense of surface soil in the neighbourhood of dwellings, is often almost self-evident. Take the case, so common in many of our northern and midland towns, where there are rows of workmen's dwellings or cottages in which the houses open at the back to a common yard, unpaved, badly drained by open gutters, and served by one or more midden privies. Who that has seen the way in which slops are thrown about such yards and the manner in which refuse may be spilled over the surface when carried to, or removed from, the common midden can doubt that a case of enteric fever in a row of houses of this sort occasions risk by way of surface soil pollution to the occupants of the remaining houses—people who, for example, must needs be liable to carry into their dwellings on their hands or boots soil upon which infectious matter has been freshly deposited and to inhale infective dust blown about the common yard? To such and kindred causes, we may well believe, is due the contrast which medical officers of health have on occasion been able to demonstrate between a heavy incidence of enteric fever on particular groups of dwellings where these sanitary deficiencies abound and its much lighter incidence upon neighbouring groups of dwellings of similar class where opportunities of surface pollution are less.

To admit, however, that enteric fever may be locally

spread by way of the diverse and obvious opportunities of infection afforded by recently and specifically polluted surface soil brings us, it is to be feared, little nearer to understanding the causation of endemic enteric fever in the cases to which we alluded above. Ability of soil to act, as it were merely mechanically, as a vehicle of infectious matter which has just been deposited on its surface does not there meet the case. A satisfactory explanation as due to soil pollution of the endemic enteric fever to which we refer seems to require the further proposition that in certain circumstances the typhoid bacillus must be capable of maintaining for weeks and months an active existence in soil—an altogether different and more recondite question. The difficulties of the subject are well illustrated in the case of the city of Chichester, where enteric fever in endemic form has been excessively prevalent for a long series of years since 1870 and has remained prevalent notwithstanding that in the greater part of the city objectionable well waters have been replaced by a safer public supply and cesspools by a modern system of sewers. Dr. THEODORE THOMSON who, with Colonel MARSH, R.E., has lately made a highly instructive report to the Local Government Board on enteric fever at Chichester, a review of which will be found on p. 219, has brought to light many facts, positive as well as negative, which taken as a whole suggest that the explanation must be that there are circumstances of soil which in Chichester, or in certain parts of it, do in some way favour the viability and active growth of the typhoid bacillus in the soil. But what are these favouring circumstances? Dr. THOMSON shows that there exist in Chichester many and diverse potentialities of pollution of soil by organic matter. But, as he also points out, the mere fact that these potentialities exist is no explanation for a special proclivity of the typhoid bacillus for Chichester soil. They are present equally in other towns with no such enteric fever history as Chichester. If this special proclivity does exist—and in our present state of knowledge the assumption seems the one most likely to accord with the facts—it is probably determined by one or other of a large number of obscure conditions which have yet to be studied in this connexion, or by a combination of them. For the subject to be adequately pursued such factors as the physical and chemical characters of the soil, the degree of its moisture, the soil-temperature best adapted to the typhoid organism, and the nature of other organisms in the soil with which the typhoid bacillus has to compete for its existence must be reckoned with. Moreover, as Dr. THOMSON indicates, no investigation, however comprehensive, of soil in relation to endemic enteric fever would have much prospect of success if it were restricted to a single locality. We trust that the Medical Department of the Local Government Board, to which we already owe so much of our knowledge of the etiology of enteric fever, may be able to extend its researches in this matter into a wider field and to investigate endemic enteric fever differentially in typical instances in different parts of the country.

MR. GEORGE EASTES, on assuming the responsible position of President of the Metropolitan Counties Branch of the British Medical Association, delivered an address entitled "Our Numbers and our Work at the Close of the Century," which is of considerable interest to the medical profession. The general conclusions to which he came on this important subject may be summed up as follows:—that there are great fluctuations within comparatively short periods in the numbers of the profession and therefore, of course, in the amount of work for medical men to do; that there is a great variety in different parts as to the proportion of medical men to population; and that of recent years there has been a marked tendency to increase in the numbers on the Medical Register whilst general medical work has, from the operation of many causes, undergone marked shrinkage in several directions. Mr. EASTES is of opinion that the work for medical practitioners to do is not likely to reach its former dimensions except under very special and temporary circumstances, as in the recent epidemics of influenza; and, speaking generally, that the outlook for medical workers is that they are likely to work under conditions of ever-increasing competition. Recognising, perhaps, that he has given rather a pessimistic forecast of the immediate future for medical men, he does his best later to correct such an impression and shows that there are some facts on the other side—happy spots where rivalry is not so keen, an ever-widening empire in which the demand for medical practitioners is felt, and the occurrence of wars in various parts which entail a sudden and an enormous increase in the demand for medical men. "Give to us peace in our time" is, we are sure, the prayer of the medical man as truly as it is that of every good citizen, but it cannot be denied that times of war create a demand for medical service.

There are places in the kingdom where, if mere numbers of patients can make practitioners happy, their bliss should be without alloy. Mr. EASTES shows that the proportion of medical men to population in Huddersfield, Norwich, Hull, and Bolton is very low. The happy practitioners of these towns have theoretically over 2000 persons dependent upon each of them for medical attendance. The other extreme is to be found in Brighton, where in 1881 there were only 741 persons to each practitioner, and where now there are only 615. The practitioners of London come next in paucity of patients, having each barely 800 persons to attend. Mr. EASTES tells us that in South Paddington, where the population has grown less by 3000 since 1861, the numbers of the profession have increased by 20 and the average of persons for each practitioner can be very few more than 300. The practitioners of these districts ought obviously to be in a very bad way, but we are not aware of any facts which go to show that they are more unhappy or less prosperous than those in Huddersfield or Norwich. Probably it will turn out that the mere number of possible patients is not the chief factor in the prosperity and happiness of the profession. It is more important for medical men to have a number of clients to whose needs they can do justice and by whom they can be adequately appreciated and rewarded. It must be remembered that these figures are subject to fluctuation in every locality, while the proportion of medical men to their patients throughout the kingdom is also constantly changing. For

example, in 1881 it was as high as 1718; now it is as low as 1393, which is almost identical with the proportion in 1861. Mr. EASTES quotes the late Dr. FARR as having 25 years ago said that the medical profession would not grow in proportion to the population and as having feared that "there was imminent danger that medical attendance might become quite inaccessible to vast numbers of people." Dr. FARR is not the only authority who has been thus apprehensive. The late Lord PLAYFAIR used to address warnings to the same effect to those who advocated bold measures for straitening the gate of the medical profession so that few should enter it. And undoubtedly it would be possible to carry such measures too far. The medical art, it must be remembered, is a necessity to all classes. The poor and the humble have the same need of it as the rich and the luxurious classes. But there is no immediate need for much anxiety on this subject, for the additions to the profession amount to hundreds every year. There are, however, some new facts in the problem which must not be overlooked. In 1861 there was a large class of unqualified assistants who did, roughly perhaps, a third or a fourth of the work of general medical practice. That element has been eliminated by the action of the General Medical Council or is in course of elimination. Medical work has been multiplied in various ways by the specialisation of medicine and by the great developments of medical education. The growth of wealth and of commerce involves an increased demand for medical service in all its branches—sanitary, medical, surgical, and special. Then there is the great development of our empire which throws so much serious responsibility on us for the welfare of those by whom it is extended and of the communities which come by their agency under our rule and care. Nothing in the last century can exceed the significance of the events which are happening while we write, teaching us that the millennium is yet distant and that enormous medical and surgical and sanitary problems will have to be solved before Africa and China can be brought within the pale of civilisation as we understand it.

Mr. EASTES thinks that the work of the general practitioner is much less than it was 30 years ago and that it is likely to continue so. The isolation of infectious disease and its treatment by the State, the abuse of hospitals, the multiplication of cheap dispensaries, the growing tendency of the public to take their advice from consultants and specialists of all sorts, all tend to lessen the work of the general practitioner and to lead Mr. EASTES to the conclusion that the profession is overstocked. Such facts are very important and call for much consideration, but we do not regard them as ultimate facts that are to dominate and degrade general medical practice for all time. In the very nature of things the general practitioner must always be the first and chief resource of the public needing medical advice. Palpable abuses which affect him injuriously will not last for ever. The general practitioner must meet the competition of consultants by dignified protest or by specialising his own education. He has only to perfect himself as a general practitioner to make himself indispensable in every community and to make the consultant in nine cases out of ten a luxury.

Annotations.

"Ne quid nimis."

THE CENTENARY FESTIVAL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON Thursday, July 12th, Sir William Mac Cormac was unanimously elected President of the Royal College of Surgeons of England for the fifth time in succession. No one has previously held the position for so many years, although the late Sir William Savory was President from 1885 to 1888. Thus Sir William Mac Cormac this year holds an exceptionally honourable post. The centenary festival of the Royal College of Surgeons falls in troublous times. One hundred years ago the shadow of the domination of the First Napoleon, who for a brief space held continental Europe under his feet was just beginning to obscure the sun of liberty. To-day Europe and the United States of America stand confronted with the shadow of a far more barbarous tyranny arising from that race of which 1500 years ago Attila was the incarnation. But the forthcoming festival is in reality a peace congress, a living testimony to the advance of the art and science of healing, and it is fitting that its chief should be one so lately returned from ministering on the battle-field.

THE TRAGEDY AT PEKING.

AFTER many days of conflicting rumours in which men expressed opinions and hopes that their reason refused to justify it has been borne in upon the civilised world that every man, women, and child in Peking foreign to China, and every Chinese native known to be in personal or religious sympathy with them, is dead. What horrors may have accompanied those deaths it is best not to conjecture, while the stories that have been circulated as to the way in which the women and children met their deaths within the walls of the British Legation are founded entirely upon imagination. Letters have been received in England speaking of revolvers carried by women in anticipation of the worst, while it is stated upon good authority that Lady Macdonald, the wife of the British Minister, went armed with poison even before the actual outbreak took place, knowing that she might need it for herself and for her children. In this course she cannot have been alone, but the actual events of the terrible closing scene are still unknown to us and may never be other than unknown. There have been massacres before where the natives of savage countries have wreaked their hatred suddenly upon the foreigner in their midst, but there has been nothing in history absolutely resembling the tragedy of Peking. England has had experience of terrible outbreaks of savagery at Cawnpore and elsewhere during the Indian Mutiny, and we have ever since had thrown in our teeth by European nations the penalties we exacted in reprisal and in reassertion of our authority. Now each nation of Europe having a political representative at Peking knows that that representative, with wife, children, and household, has been butchered, knows that every citizen it has sent out to spread its commerce, to preach its religion, to disseminate its science and its civilisation has either been slaughtered in the Chinese capital or in some other part of the Chinese empire stands in imminent danger of a hideous death, and the spirit that is abroad is certainly not one of meek forgiveness. Europe will exact a reckoning, though to whom the bill should be presented is, in the present state of our information, obscure. Every day makes it clearer that

the outbreak is not merely the work of a secret society in rebellion, too strong for the Imperial Government to cope with, but a national movement with which many in high places connived, which was incited and abetted by those who at different stages have professed hostility towards it, and with which the majority of those responsible for the government of the country sympathised in their hearts if not with their voices. In such circumstances it seems inevitable that there should be a war in which the combined forces of Western civilisation will meet the vast hordes that an ancient Eastern civilisation—for up to a point the Chinese are a civilised nation—can bring against them, and that such a war should be primarily a war of vengeance. Chinese cruelty and treachery have been brought home to European nations before, but an act that simultaneously involves them all with America and Japan in the cry for reprisals must, if the act is brought home to the Chinese Government, produce extraordinary consequences. The Chinese may possess an ignorant mob, but the mob has been led in its fury and instigated to its crime. Those who govern China are not uncivilised savages and cannot claim indulgence as such. Centuries have elapsed since their ancestors first rejected our envoys and refused to let them reside at their capital; since then they have for years had their own accredited representatives at European courts, while Chinamen of all classes have been brought into contact with Europeans all over the world; and yet the blow has been allowed to fall without warning, and as far as can be judged every artifice of Oriental duplicity has been employed to conceal the truth as long as concealment was possible. It may be easy to justify the resentment of the Chinese people at the encroachments of foreigners, or at what it has regarded as such; and to explain that the efforts of missionaries to propagate Christianity have not only been comparatively fruitless but have given opportunity for rousing all classes against all strangers whether missionaries or not, but the nations now apparently united in a common cause will not be easily persuaded that the tragedy of Peking, and others perhaps of less magnitude but no less terrible, that may follow, could not have been averted or delayed by those who can be made in some degree responsible. At present all the principal nations of the world seem in the last years of the nineteenth century and within a year of an international peace conference to be on the brink of a war that will demand for its successful prosecution all the resources of their science and civilisation, while all the moderating influences of Christianity and civilisation will be needed to limit its duration and mitigate its horrors. Possibly not till it is ended shall we know at all accurately what has already taken place, while it seems likely that the fate of individuals will, perhaps mercifully, remain for ever veiled. Among these are members of the medical profession. Some have been named already and our readers must be able to reckon others among their friends or acquaintances who may, or may not, have taken refuge in the capital hoping for comparative safety there. Others, again, at present survive, settled in towns that once seemed to be safe or scattered and isolated in spots where they hoped to benefit fellow-men, combining mission work with medicine. For all these the outlook is a very grave one, and if we may be cheered in time by finding that the rising has spread less widely than has been anticipated we may, on the other hand, still have news to face even worse than that which has come to hand. To all those, therefore, who have given up hope for those whom they loved, or who are suffering from the heavy strain of anxiety on their behalf without news to relieve it, we tender our deep and sincere sympathy.

THE LUNACY SCANDALS IN ST. PANCRAS.

As we announced in our issue of July 14th the Local Government Board by means of their inspectors, Mr. H. Lockwood and Dr. A. H. Downes, opened an inquiry on Tuesday, July 10th, into the alleged irregularities which have recently taken place with regard to the certification and removal of lunatics. The inquiry closed on Thursday evening, July 12th, and the evidence taken was chiefly that of parish medical officers and of relieving officers. Evidence showed that the relieving officers expected to get "tips" from both parish medical officers and from the proprietors of private lunatic asylums. If they did not get their tips from the parish medical men these latter got no lunatics to certify. Mr. Lockwood adjourned the inquiry, so at present we shall not comment upon the matter, it being practically *sub judice*. We may mention, however, that the Local Government Board have issued a letter to clerks of boards of guardians in which, without referring by name to any particular parish, they say that they know that payments have been received by relieving officers from parish medical men and proprietors of licensed houses in connexion with the certification and admission of lunatics in at least two parishes. Further, they have reason to believe that this practice exists in other parishes. The Board therefore wish it to be understood that they consider the practice as indefensible and that no officer offending in future should be allowed to retain his post. This expression of opinion does not mean that the past will be condoned.

SIR WALTER FOSTER AND THE MEDICAL ARRANGEMENTS AT THE SEAT OF WAR.

REFERRING to an annotation in THE LANCET of July 7th Sir Walter Foster courteously furnished us with a reference to the seventh edition of Parkes's Practical Hygiene as the authority for his statement that in the opinion of the late Professor de Chaumont the amount of hospital accommodation to be provided for an army on field service should not be less than 25 per cent. We have now had the opportunity of verifying the correctness of Sir Walter Foster's quotation, which we gladly acknowledge. This amount of hospital accommodation struck us at the time as being very large and as impracticable, if not, indeed, unnecessary, for a force operating under the conditions and circumstances that ordinarily obtain in modern warfare. We desire to add that we are not only justified in holding that opinion, but in now claiming it as that also of those responsible for the subsequent edition (the eighth) of Parkes's Hygiene, and we can only regret that Sir Walter Foster did not prosecute his inquiries a little further by quoting the latest edition of that work in making a public statement, in which case he would have escaped being misled himself and of unwittingly misleading the House of Commons. The seventh edition of Parkes's Hygiene, edited by Professor de Chaumont, was published in 1887. A good deal has happened since then. In the succeeding edition (the eighth) published in 1891 and edited by Professor Lane Notter, the present professor of military hygiene at Netley, we read: "*Amount of hospital accommodation.*—This must not be less than for 10 per cent. of the force, with reserve tents in rear in case of need." This quotation is from page 674, Chapter VI. We could understand that for exceptionally unhealthy climates and seasons an exceptional rate of hospital accommodation might, of course, be necessary, but for an army of a strength of 200,000 operating in a climate like that of South Africa 25 per cent. seemed to us an unreasonably high estimate. But assuming that there had been hospital accommodation for 50,000 sick and wounded in South Africa we fail to see how it would have availed to meet such an emergency, say, as that

of a force outmarching its supplies—unless it was known beforehand where the army was going and the hospital supplies could have been sent there in advance. Be this as it may, there are a few other points to which we may take this opportunity of referring in connexion with the mortality of typhoid fever. If Sir Walter Foster will refer to the *Times* of July 12th he will find a communication from Mr. Sydney Holland in which Mr. Holland seeks to correct an erroneous inference deducible from a previous letter. Mr. Sydney Holland gives a statistical table of typhoid fever cases admitted into the London Hospital from 1895 to 1899 (inclusive) from which it will be seen that the rate of mortality per cent. among males between 20 and 30 (soldiers' ages) was 22·35. As regards Brand's statistics they do not seem to us to be to the point, unless the ages of the patients are stated and we know how many of the shortest and mildest forms of fever were included to make up the totals. If we recollect aright, too, those tables were to illustrate the beneficial results of the cold-bath treatment of typhoid fever, and we can scarcely suppose that Sir Walter Foster expects that this method of treatment can be had recourse to under all the conditions of war.

THE NEW INFIRMARY OF ST. MARY'S, ISLINGTON.

ISLINGTON justified its old title of "merrie" by the way in which its inhabitants received the Duke and Duchess of York on Monday, July 16th, when they went to open the new infirmary which is expected ultimately to have accommodation for 800 people. Nothing could be more satisfactory than the opening ceremony, and nothing could be more sensible and to the point than the address of H.R.H. the Duke of York. Whatever difference of opinion there may be about the expediency of providing palatial residences for paupers, there can be none about the propriety of providing infirmaries for the sick and dying poor with every amenity that can mitigate their suffering and give them a sense of being cared for and considered. The guardians of Islington confess to an expenditure on this institution of £273,000 and we shall not be far wrong in reckoning that it will cost the ratepayers £300,000 before it is finished. This is a royal expenditure and could scarcely have been exceeded by the Metropolitan Asylums Board. But it is not too much if the ratepayers and the poor for whom they cater have got a *quid pro quo*. We are not satisfied on this point. The beauty of the whole is spoilt by the way in which the various parts of the brick building are jumbled together. There is an absolute absence of all grace of structure and architecture. The operating theatre and the laboratory, which should have been cheerful and light chambers, were dark and dismal even in the bright summer day of the opening ceremony. It is perhaps premature to judge the operating chamber, but its essential faults of structure and lighting and the absence of safeguards against septic organisms are very obvious; such safeguards, too, are conspicuous by their absence in most of the wards. It is gratifying to us to be able to hope that there are no medical men on the building committee who must bear the responsibility of this building, which might have been graceful and perfect in its way, and ought to have been so considering the money of the ratepayers which has been lavishly spent upon it, but which in point of fact is in every way disappointing.

MR. LONG AND RABIES.

IT is probable that no one in England has been more abused by a certain section of the dog-owning public than has the present Minister of Agriculture. The application of the muzzling order has been the cause of a good deal of excitement at various times, but the results which have been attained have fully justified the means employed. There is less rabies in Great Britain than there has been for many years; in fact, it may be said to be practically stamped out. This splendid result, which has been achieved over a terrible disease at the inconvenience only of the canine world, is solely to be attributed to the energetic measures taken by Mr. Walter Long and his veterinary advisers, and too much praise cannot be given to those gentlemen for what they have done. There is no more awful disease, either in man or animals, than rabies, and the enviable position which has been attained for this country in being able to declare itself practically free is one which must be maintained at all costs. Strict quarantine regulations with veterinary and police supervision for a certain period of time are annoyances which owners ought to consider as very trivial when compared with the advantages and safety that they confer not only upon themselves but also upon their pets. According to the returns of the Board of Agriculture there were only nine cases of rabies reported in 1899, whereas the corresponding numbers in 1896, 1897, and 1898 were 438, 155, and 17 respectively in dogs alone, whilst in other animals no cases occurred in 1898 or 1899, but in 1896 and 1897 the numbers were 22 and 36 respectively. These statistics speak for themselves and although the time cannot be very far off when the muzzling order will be removed from every part of England it is to be hoped that if any error is made in this direction it will be rather on the side of safety than otherwise. Mr. Long has indeed earned the gratitude of the country for the extinction of rabies alone, and as a nation we are to be congratulated upon having a Minister of Agriculture who has so perseveringly carried through to a successful termination a measure which for a time caused a great outcry and brought down upon his head a violent torrent of sarcastic criticism.

THE EPIDEMIC OF FORTUNE-TELLING.

So long ago as March 31st last a person described as Zuleika Cavalier, aged 30 years, and married, was brought before the magistrate at Marlborough-street and charged with telling fortunes at an address in Bond-street. After being remanded she was eventually fined £25 and ordered to pay £10 costs, upon which she gave notice of appeal. In view of the appeal we did not criticise her case at the time, but now that Mr. McConnell, Q.C., sitting as Chairman of the Court of Quarter Sessions at Clerkenwell, has dismissed the appeal with costs we are at liberty to do so. The prosecution of gypsies for cozening servant-maids out of their wages by promises of wealthy suitors and other desirable prospects are more or less frequent, but it has been a matter of observation that of recent years persons professing to tell fortunes for the benefit of those moving in higher social circles than these have been permitted to ply and advertise their trade in the more fashionable streets of London and other towns with openness and impunity. We need not recapitulate the evidence given against Zuleika Cavalier, but we note that among the materials for her conviction found by the police in her room was a correspondence with a married woman who had inquired when she would be a widow and also as to who would be her next husband. It seems clear from such instances as these, if it required demonstration, that there are women who need protection from the suggestions of the fortune-teller apart from those whose credulity may merely cause them to suffer in pocket. The various devices most often associated with the ambition to pry into the future are of venerable antiquity, but Zuleika Cavalier does not seem to have earned the £1500 a year with which the police credited her by following

the methods of the orientals in whose costume she masqueraded. Perhaps her visitors were so numerous that she had no time to linger over her divination. She did not use the tarot or tarots, cards in a pack of 78, a very ancient device popular with gypsies of all ages and, as it seems to us, a somewhat mechanical means of lifting the veil of futurity. Nor did she produce in herself hypnotic conditions by gazing into the crystal ball or the ink-pool, a far more imposing and at least as venerable a form of divination; nor did she indulge in an exhibition of cheiromancy, lithomancy, pyromancy, or kapnomancy. According to her own account she adopted a plan which if not picturesque was businesslike and not altogether without precedent: she shut her eyes, ejaculated a prayer, touched the hand of her subject, and proceeded forthwith to see "mental pictures" on his behalf. These pictures in the case of the Hon. A. Macdonnell, to whom the public is indebted for the recent prosecution, were of a decidedly definite rather than of an impressionist character, one of the incidents foretold to him being that he would shortly receive a portrait of one of his ancestors anonymously and would find at the back of it a piece of paper leaving him a fortune which would partially atone for a great wrong done to him by an ancestor a long time ago. A lady who has extracted £1400 or £1500 a year from the credulous by simple and romantic tales of this hackneyed type will not find it difficult to pay the fine inflicted on her. She will, however, bear in mind that the powers of the magistrate who sentenced her were not limited to the power to inflict a fine and that moreover on a second conviction for a similar offence they are considerably increased, as he is then empowered to deal with her as an "incorrigible rogue." At the same time she will have good cause of complaint if after she has herself been punished according to the law her numerous rivals in trade are allowed to flourish in defiance of it.

REST-HOUSE *v.* WORKHOUSE.

WE have frequently pointed out that our modern Poor-law, forced into existence as it was by the spoliation of the monastic institutions which formerly ministered to the poor, was hopelessly defective in one respect—namely, that no line of demarcation as to treatment was drawn between those who had failed in life from sickness or bad fortune and those who were idle, drunken, and improvident. That a man or woman who had worked all his, or her, span of working life should when no longer able to work be relegated to the same place and the same treatment as the tramp and the loafer is not only inhuman but immoral, and we therefore offer our warmest congratulations to the guardians of the poor of St. Olave, Southwark, for the new departure which they have taken. The new rest-house, for so it should be called, is situated at Ladywell, and was formally opened upon July 12th by the Prince and Princess of Wales. The total extent of the site is 34 acres and there is accommodation for 812 persons. Although, of course, the institution is still under the Poor-law the inmates will be treated in a manner as home-like as possible and the stringency of workhouse regulations is much relaxed. In the words of Mr. Shand, the chairman of the board of guardians, the building is to be a "home of rest for those worn-out sons of the State who through no fault of their own have come to poverty in their old age and are in need and necessity." The Bishop of Southwark opened the proceedings with prayer and the Prince of Wales in a few simple words expressed his pleasure at the new departure in the treatment of the aged and infirm poor. The Bishop then pronounced the benediction and the proceedings ended. Ratepayers rightly grumble at the enormous sums which they are compelled to disburse for educational experiments, but no one will complain at having to pay to make the close of life easier for those who have reached the last stage of their pilgrimage here.

A FRENCH CRITIC ON BRITISH ARMY SURGEONS.

M. JEAN CARRÈRE, the able special correspondent of the Paris *Matin*, is now in South Africa. In the course of his very interesting letters he has on several occasions spoken in high terms of the British army surgeons with whom he chanced to make acquaintance. In a recent letter he described a visit to the hospital ship at Simonstown where he went to visit a French prisoner, M. du Feissal, who was wounded by the same shell which killed Colonel de Villebois-Mareuil. On reaching land again M. Carrère writes as follows, and in translating we seek to preserve his colloquial unconventional style:—

"We entered an hotel where they served us with unnameable things which we watered with a doubtful Moët violently acidulated. Then who should turn up but Dr. Carré whom we had searched for all the day. Thus we must never despair of anything. I am introduced. Dr. Gerard Carré, as his name indicates, is of French origin. He is young, about 30, fair, aquiline nose, fine beard, blue eyes. We drink and are 'chums' at once. He speaks to me about his patients with a fraternal gentleness that touches me and goes straight to my heart. I then remember the letter of Dr. Roë. What delightful beings these doctors are; and if ever I have said any evil about them I tender to them all collectively my apologies. During my journey I have frequented many of them and I have taken to love them sincerely. Evidently they do not cure death; but really, is that quite necessary? In my opinion they do better than this. They bring us the illusion of the life everlasting. And then, and above all, they are men of heart. From whatever country they may come they are all the same. The habit of living on the frontiers of humanity has conferred on them all pitiful and indulgent souls; and in the perpetual tumult of passions and conflicts, between men and races, they are the link of all possible concord and form in their immense federation of the Red Cross the International of Mercy."

ADULTERATED VINEGAR.

THE addition of sulphuric acid to vinegar, though in small quantity, is apparently still practised according to the recent report of the medical officer of health and public analyst for St. James's, Westminster, Dr. James Edmunds. He reports four cases dealing with this impurity in vinegar which were "tenaciously defended by manufacturers standing in the background." Convictions, however, were obtained in all the four cases. The chief question at issue in these cases is, it seems to us, whether such an addition is injurious. In a great number of instances there is no evidence forthcoming to show that the use of substitutes or the addition of preservatives or foreign substances is actually injurious to health, but we have always maintained that unless the purchaser is supplied with exactly the article which he asks for fraud is committed. In other words, if an article is substituted for the one demanded a case for prosecution is immediately established, although the substitute may be perfectly wholesome and non-injurious to health. These observations apply to vinegar. A pure malt vinegar should be nothing but what is in reality pure beer soured by acetic fermntation. But until the law states very precisely what this and other articles should consist of the increasing tide of substitutes will never be stayed. We doubt whether such a requirement will ever become a law of this country; it would not be practicable to enforce and it would be a source of great inconvenience, especially to the poorer class of consumers. The enormous increase in the consumption of food entailed by an ever-swelling population in our big towns and the demand for cheaper articles have brought about an

inevitable result—the production of various articles of food on a much larger scale and at a much cheaper rate. The materials used of yore have thus necessarily given place to substitutes which in their way are good and wholesome enough, although they cannot be regarded as conforming to the standard of the article produced in the time-honoured way. Beer may be quoted as an example. There is very little beer produced in this country which is brewed entirely from malt and hops. Both grain and bitter substitutes are employed and these produce an excellent and wholesome beverage, but it is not beer if we accept the definition of that article of consumption as being a fermented infusion only of malt and hops. We are inclined to take the view that the object of manufacturers on the whole is more to effect economy and to supply an attractive and uniform article than to create mischief. Indeed, in some instances different modes of manufacture have been adopted in accordance with modern scientific knowledge which have resulted in a better product. Though, strictly speaking, such recourses are not absolutely necessary, yet for all modern practical requirements they have become indispensable. It seems to us that there should be no difficulty in deciding when a manufacturing practice is objectionable or upon the suitability of a substitute for human consumption, while there can be no doubt at all as to the course to be taken when an article of food is proved to have been misnamed. This is exactly one of those matters with which we had hoped that the court of reference which it was suggested should be appointed to control the operations of the new Food and Drugs Act would deal.

EMPHYSEMATOUS GANGRENE FROM INFECTION BY THE BACILLUS AEROGENES CAPSULATUS.

IN 1891 Dr. Welch of the Johns Hopkins University reported the discovery of a gas-producing bacillus in the blood and tissues of a man who died after rupture of an aortic aneurysm. In 1892, with Nuttall, he published a study of this organism which he named the "bacillus aerogenes capsulatus."[1] It is one of a number of organisms capable of producing gaseous necrosis of living tissues—emphysematous gangrene. Koch's bacillus œdematis maligni is another organism of this group. Recently we have referred to cases in which gaseous abscesses followed hypodermic injections from infection by an organism discovered by Veillon and Zuber in various fœtid and gangrenous abscesses and termed by them the "bacillus perfringens."[2] In the *Boston Medical and Surgical Journal* of June 7th Dr. Paul Thorndike has described two cases of infection with the bacillus aerogenes capsulatus. A man, aged 45 years, fell to the ground from a height of 10 feet, sustaining a compound fracture of both bones of the forearms. Under ether the wound was thoroughly cleansed with sublimate solution and a sterile dressing and plaster-of-Paris were applied. At the end of the first day the plaster-of-Paris was removed in consequence of the pain. There was semi-delirium and the temperature was 102° F. On the following day cyanosis of the fingers and great swelling and emphysema of the forearm were present. On the third day he failed markedly and the emphysema extended to the shoulder and chest. Amputation was performed at the shoulder-joint. Both flaps were emphysematous. He rallied well, but 36 hours after the operation the septic symptoms returned and he died two days after the operation. The arm when removed was much swollen and tense. The forearm was of a deep plum-colour and the hand and fingers were dusky-red. Bullæ varying from five to 25 millimetres in diameter, filled with clear serum, were irregularly distributed over the forearm. Everywhere below the elbow the tissues were like a cushion and the slightest pressure produced crackling. In the upper arm along the brachial trunks crackling was also present. From a puncture in the forearm serum and gas were poured out. The cut surface was gelatinous and in parts semi-diffluent. Sections from several areas in the forearm showed its invasion by a long bacillus which had all the characteristics of the bacillus aerogenes capsulatus. In the spleen microscopical examination showed several foci of the bacillus. In the second case a man, aged 33 years, had compound fracture of the leg. On the third day the foot was cyanotic and painful and bluish mottled spots appeared on the leg. On the fourth day the leg was covered with blebs and there was a foul discharge from the wound. Emphysema appeared and extended above the middle of the thigh. Amputation was performed at the middle of the thigh through diseased tissue and drainage was provided. On the seventh day emphysema reached Poupart's ligament. Under ether long incisions were made in the crepitating area and the disease ceased to extend. Recovery ensued. Dr. Thorndike insists upon the necessity of operating as early as possible in these cases, and he thinks that the operation in the first case was performed 24 hours too late.

THE CHEMISTRY OF SOOT.

THERE is a very general impression prevailing that soot is simply carbon, but chemists have long known that though carbon is its chief constituent yet there are present other elements, amongst which hydrogen and nitrogen may be counted as of some importance. Indeed, it has been stated that soot is an impure hydrocarbon containing a very large proportion of carbon relatively to the amount of hydrogen. Soot possesses some peculiar properties. As everybody knows, the fact of the very characteristic and so-called smell of soot being in a domestic apartment generally portends wet weather or it may occur simultaneously with the onset of hot weather. It is probable that a reduction in the height of the barometer and an increased amount of moisture in the air are conditions which combine to expel a substance from the soot of our chimneys the peculiar smell of which is so noticeable in the room. The smell suggests ammoniacal compounds, and we are not surprised to find that a recent analysis has shown that soot contains no less than 7·4 per cent. of ammonium salts. This fact amply accounts for the value placed on soot for agricultural purposes. Again, it may be remarked that soot on burning in a more or less confined area (as in the case of a chimney on fire) evolves a characteristically persistent and most nauseous smell. This peculiar characteristic is likely enough due to the presence of nitrogenous organic compounds. Needless to add it is very probable that partly on this account the horrible fumes emitted from a chimney on fire are intensely poisonous; and on this ground alone punishment should be severely dealt out to the person who allows this disgusting pollution of the air to take place.

A FORGOTTEN PHYSIOGNOMIST.

AT the present time the study of physiognomy has dropped so much out of sight that we are apt to forget the exaggerated importance that was attached to it in the distant past. The first student of physiognomy on record is Aristotle, who invented the term to designate the art of discerning character in man by means of the features of the face. Cicero was a notable physiognomist, but it was not until the dark ages began to be illuminated that the subject attracted popular attention, enlisting numerous exponents. In the eighteenth century Le Cat and Pernethy both produced elaborate essays on the subject, inaugurating the system

which is at present followed, but the best known authority during this period is Lavater who was led to undertake "the study of Physionomies" by "the turn of the neck" in a soldier who happened to pass by a window where the "citizen of Zürich" was standing with his friend "Mr. Zimmerman, physician to his Britannick Majesty of Hanover." Lavater informs us that he "began oftener than once to study the authors who have written on Physiognomy, but was soon disgusted with their verbose jargon ..... most of them chiefly pilfered from Aristotle." There is, nevertheless, an earlier physiognomist whose work, whatever may be the verdict as to verbosity, is certainly not jargon. Long buried in oblivion this remarkable volume, which bears the date of 1615, was brought once more to light a year or two since by Professor Mantovani of Bergamo. The name of the forgotten author is Samuel Fuchsius, but whether or not he was a relation or descendant of the celebrated botanist is uncertain. On his title-page he informs us that it is his purpose to treat of the "symptomatic values of the forehead and eyes in determining the characters as well as the ntellectual and affective aptitudes of men." Besides an introduction the treatise comprises 34 chapters, of which 15 are devoted to metoposcopy and 19 to ophthalmoscopy, both divisions being profusely illustrated by portraits, plates, and diagrams in the most approved style of the period. "I expose," says Fuchsius in his exordium, "if not perfectly at least to the best of my ability and in all honesty, the substance of physiognomy: if many bewail the sad fates of Cato and of Cæsar, the victims of adversity, how much more rational would it not be to explore the destinies of our own contemporaries and to foresee with quasi-divine prescience how much of criminality and how much of rectitude each one of us bears within him? You may, O Mortals! entrench your voices behind the double rampart of your lips and teeth, but for all that your foreheads and your eyes will continue to afford an infallible means of detecting your inmost thoughts in all their bareness, devoid of all the disguises of fiction." Before entering into details Fuchsius at considerable length, and exhibiting a quaint mixture of determinism and pessimism, maintains that since all qualities, good, bad, or indifferent, are part and parcel of human nature it follows that the means of giving outward and visible expression to those he possesses must necessarily exist somewhere in each individual's body. Then taking his examples from among the sculptured effigies of historic personages he proceeds to substantiate with more or less success the correctness of his theory. Foreheads he divides in the first place into large and small. "A small forehead is the index of a small, narrow, feminine mind, and rarely will the owner of such an one be found endowed with the qualities which conduct to the temple of glory and renown: he will be irascible, curious, prone to avenge himself, and credulous of falsehoods and old wives' tales." Next the author passes in review a whole regiment of foreheads of different shapes and sizes—long, broad, low, round, square, projecting, retreating, &c. Criminals with ambitious proclivities, such as assassins and highway robbers, have narrow foreheads; in fact, it is in people of this description that the minimum diameter is to be met with. A low-type forehead shown in one of the illustrations is remarkable as presenting an almost complete collection of the modern stigmata of degeneracy; and equally worthy of observation it is that Samuel Fuchsius in the seventeenth century should have regarded a profusion of coarse hair as usually associated with a feeble or disordered intellect. Among many other interesting points commented upon in the first part of the book the wrinkles in the foreheads of melancholiacs and also in those of the newly-born children of elderly parents may be mentioned. In the second part, under the head of Ophthalmoscopy, Fuchsius again displays wonderful perspicacity. More even than the forehead, he says, the eye is capable of betraying the most delicate play of passion in the human mind, as well as of indicating with the utmost preciseness the degree of intelligence which the individual possesses. In considering the eye we should take note of its accessory in addition to its essential parts. Heavy eyebrows are an attribute of robbers, liars, and homicides. When straightly drawn they denote sadness; if arched, arrogance; if bent inwards towards the root of the nose, austerity. Large eyes reveal laziness; small eyes are found in cowards and misers. An episcleral circle marks premature senility; strabismus is often the outward sign of partial amentia; while pigmentary anomalies in the iris betoken eccentricity and imbecility. "Eyes which are apt to tremble and be convulsed upwards indicate the sacred disorder, but are likewise a characteristic of cruel men, of murderers, and of all persons possessed by malignant spirits." The passions and affections, without exception, have their indices in the human eye. The descriptive list supplied by Samuel Fuchsius is admirably conceived and executed, but its great length renders it exclusory.

THE EARLY RECOGNITION AND TREATMENT OF NEUROSES IN CHILDHOOD.

DR. CHARLES L. DE MERRITT deals with this important subject in a paper published in the *New York Medical Journal* of June 16th. He refers to the common existence of hysteria and neurasthenia in children and urges the importance of recognising the symptoms early, as he believes that a majority of such cases among adults have their insidious beginning in childhood. A medical practitioner who is consulted by parents about an irritable, highly-strung, eccentric child will often give some commonplace advice about diet, rest, &c., and generally tell the parents that "the child will out-grow it," which assuredly he or she often will not. The neurotic element or morbid taint present is not detected in time, and for want of proper moral and hygienic restraint the child grows and reaches maturity with his or her nervous force already exhausted, "another recruit for the army of neurological wrecks whose existence is one of the most appalling problems of present-day society." In such cases it is often possible to trace heredity both as a direct and an indirect factor. By the latter is meant the deleterious influence exercised in infancy and early childhood by neurotic parents who scold and nag their children incessantly and yet have not the will power to enforce real discipline so that what little of mental equilibrium the child may possess is speedily destroyed. As regards overstudy in school Dr. Merritt does not regard it *per se* as the chief factor of breakdown in school children. "German children," he says, "study harder than ours, yet they collapse much less often because their home life is more sedate and precocity is suppressed, not encouraged as is too often the case in American homes." Lack of exercise and of fresh air are prolific causes of neurotic troubles. Other causes are poor or insufficient food, anæmia, and the infectious fevers. The symptoms most frequently met with are insomnia and pavor nocturnus, great irritability of temper and disposition, a tendency to lie and to impose upon people for no apparent reason but the love of so doing, masturbation, fits of crying and paroxysms of passion upon little or no provocation, habitual feigning of illness, and an undue desire and craving for sympathy. With reference to treatment the parents must first be scrutinised, the anomalous symptoms must be traced to their source and treatment must be adopted accordingly as experience directs. Rest from school study must be prescribed with caution, for the relaxation of the mental and moral discipline of school life may harm rather than benefit a young

hypochondriac who is disinclined to associate with his fellows, who prefers solitude, and who broods over his feelings. The gymnastics now taught in most schools constitute a very valuable means for promoting physical health and they deserve encouragement. If the parents are themselves neurotic and hypochondriacal it must be explained to them how such defects react upon the child and how the mischief of imitation should be obviated. Drugs are of secondary importance. Bromides and hyoscyamus may be used for a time, and warm sponge-bathing at bedtime is also useful. The distinction between hysteria and neurasthænia is of little practical importance in children and does not affect to any extent the treatment to be pursued.

A MEDICAL MAN'S HUNTING ADVENTURE.

IN his interesting and profusely illustrated work, "Under the African Sun" (London: William Heinemann, 1899), Dr. Ansorge graphically describes an exciting adventure which happily was not attended with the serious consequences that at first seemed probable if not inevitable. While he was crawling away "on all fours" from a wounded rhinoceros the author's Martini rifle which he was dragging along with the left hand suddenly exploded, its muzzle at the time being pointed at his left foot and almost in contact with it. He supposes that the trigger caught in some stubble, but be this as it may the bullet passed clean through his foot drilling a hole at the base of the great toe where it joins the metatarsus. The two natives who were with Dr. Ansorge at once jumped up and ran away, whereupon he too jumped up and ran, but within 50 yards or less he sank to the ground overpowered by the pain. Fortunately the vision of the rhinoceros is very dull; the animal galloped off without seeing any of the party, and so the wounded man was able to attend to his injury. With great difficulty he succeeded in removing his heavy shooting-boot and blood-stained sock, but by that time the toe was cold, blue, and apparently dead. Tearing off a long strip of cloth to serve as tourniquet and bandage, Dr. Ansorge contrived to staunch the flow of blood, and as he luckily had a light network hammock with him his servants found no difficulty in carrying him back to Fort Smith. "What worried me on the way," he adds, "was not so much the pain as the thought that, if the great toe was really done for, I should have to amputate my own toe, not a very pleasing prospect; or, as an alternative, something even more disagreeable to contemplate, I should have to ask one of the officials at the fort to cut the toe off, and not one of them had the necessary surgical knowledge." However, "all's well that ends well"—during the three hours occupied by the return journey the collateral circulation had time to establish itself, and eventually under simple antiseptic treatment the digit became for all practical purposes as good as ever. At first there was considerable stiffness of the joint, but the long tendon upon which so much of the movement of the hallux depends became thoroughly reunited, although it had been completely cut through by the bullet, and in the course of a few months the parts had regained most of their original efficiency.

THE NEW UNIVERSITY OF LONDON.

THE members of the respective faculties of the new University, whose names are published in the regulations, are requested by Sir H. E. Roscoe to attend on Oct. 12th at the University Buildings, South Kensington, at 4 P.M., for the purpose of the elections under the statutes. The elected members will serve upon the Senate, the first meeting of which is intended to take place on Oct. 24th. The members are thus divided in the various faculties: Theology, one; Arts, four; Laws, one; Music, one; Medicine, three; Science, four; Engineering, one; and Economics and Political Science, one. In addition to the members elected by the faculties, 16 will be elected on Oct. 9th by the graduates in Convocation, of whom two will be elected by the registered graduates in Medicine and Surgery, six in Arts, one in Laws, one in Music, and six in Science.

THE NEW PSYCHOLOGY.

DR. HENRY MAUDSLEY has published in the July number of the *Journal of Mental Science* a valuable contribution relating to the new psychology from a critical standpoint. Dr. Maudsley at the outset points out the various and somewhat arbitrary distinctions that have been drawn between the titles "mental science," "mental physiology," "psychology," and "mental philosophy." Under these titles we have at the present day "four formidable systems dealing with one and the same subject, yet having different names, pursuing separate paths, speaking different and mutually unintelligible languages, often hostile in attitude towards one another, almost as averse to meet as parallel lines." Leaving this subject, on which a good deal more could be said, Dr. Maudsley referred to two methods of research lately in vogue and large with promise—viz., the systematic study of child psychology and the so-called psycho-physical research. The results accumulated by child-study require to be interpreted with great caution. It is difficult for the adult to understand correctly and rightly to construe by the light of his ripe thought and feeling, his formed and conscious thought, that which is only forming and scarce conscious in the immature mind of the child. "In the immature mind the word, like the underlying idea or feeling, is simple, single, without associations, almost detached, naked, so to speak, whereas in the mature mind it is involute, containing layers on layers of experience, having manifold associations which are roused into more or less conscious thrills, emotional or intellectual, by every use of it." To strip off or abstract so much of the structure of his own mind as to reduce it to the simplicity of the child-mind, and then to use his so mutilated mind to observe and interpret, is a matter of exceeding difficulty. "He would find it easier, I think, to walk the walk and talk the talk of his infant." To give an illustration: When the child asks the astonished father, "Daddy, why doesn't God kill the Devil?" he puts as simple, correct, and natural a question as he would do were he to ask, "Why does not daddy kill the rat?" One question is not a whit more wonderful than the other. The child has been taught to picture God as a big, strong Being, living out of sight high up above, Who can do whatever He will, loving good deeds and good persons, angry with those who are naughty and do wrong—to picture Him mentally, in fact, as a kind of bigger and stronger father. And reasoning then from the particular to the particular, as incipient intelligence cannot choose but do, the child naturally wonders why God does not kill the Devil who is going about doing wrong and tempting to do wrong. The child's assertions are direct and simple, not trammelled as yet by modifying associations or vitiated by conventional errors and prejudices; therefore his utterance is sometimes singularly fresh, startling, and suggestive. Sentimental persons may detect "intuitions" and "trailing clouds of glory from afar" as they dote on children's innocent simplicities, but it is they, the enraptured gazers, who project them and read them into the child out of their own feelings, just as the fond mother watching the flicker of a smile across her sleeping baby's face projects a heavenly meaning into the purely reflex movement excited by a pleasant visceral stimulus. The real

babe, as a matter of fact, is a selfish parasitic creature, with all its instincts converging towards the animal self, exacting tyrannically all the services which, happily for it, maternal devotion likes instinctively to give. Child psychology should note and watch the performances of children and interpret them by the light of heredity and human evolution. As regards psycho-physics—the creation of Wundt in particular—its promises and expectations were very large, but the performance has been very small. In the end psycho-physics belongs more to physiology than to psychology, for the methods are physiological. Idiosyncrasy or personal equation is a complicated unknown quantity, containing several *x's*, and this enters into all equations of reaction, time, and other psycho-physical measurements. One person may feel faint because a cat is in the room, another may be poisoned by a strawberry, and a third may be unable to "contain his urine if he hears the sound of the bagpipe"; one may react deliriously to opium where another is not affected with the same dose. There are hosts of subtle and obscure factors entering into the composition of idiosyncrasy and temperament, which must always vitiate the measurements and reaction-times made on different subjects. The extensive and lengthy publications which have been issued from many psycho-physical laboratories must remain monuments of sterile industry, monumental mockeries of knowledge. An impassable gulf lies between measurements of objective reactions and the subjective state which is intangible and for which no common unit of measurement is possible. Man is too complex for psycho-physical measurements.

ARSENIC IN SODIUM PHOSPHATE.

IT must be admitted that the apparently uniform occurrence of arsenic in important quantity in ordinary phosphate of sodium is a revelation, although on reflection there is the possibility of arsenic being contained in all drugs in the preparation of which common sulphuric acid is concerned. Sulphuric acid is used, of course, for liberating phosphoric acid from phosphate of lime and the resulting phosphoric acid when neutralised with carbonate of sodium yields the ordinary phosphate of sodium. Any arsenic present, therefore, is most probably combined with the soda to form arsenate, a salt that in many respects closely resembles the phosphates. It is clear, however, that the contamination of phosphate of soda may become so marked as to render the salt distinctly poisonous. In the remarkable cases which were recently brought under the consideration of Mr. Plowden at the Marylebone Police-court, and upon which last week he delivered, as we consider, a very sensible pronouncement, it was shown that this arsenical impurity might easily amount to a dangerous quantity. The evidence that the arsenic occurred by accident or carelessness may be ignored in view of the fact recently elicited by the examination of a number of specimens of phosphate of soda which all showed the presence of more or less arsenic in the form of sodium salt. Even phosphate of soda crystals which have been supplied as chemically pure for analytical purposes have been found to contain an appreciable quantity of arsenic. There may well remain, therefore, some anxiety as to the destiny of impure phosphate of soda which was consigned before the fact of its arsenical impurity was known. The apprehension of mischief arising increases in intensity when we have regard to the fact that phosphate of soda is employed as an ingredient in a popular effervescing drink. The use of this drug in this indiscriminate way is much to be deprecated, and had it not been for the fact that phosphate of soda had been prescribed for a person under medical care it is quite probable that the presence of arsenic in phosphate of soda would still have remained undiscovered. It is not at all improbable that many persons addicted to this medicated beverage have been innocently poisoning themselves. The Pharmacopœia says nothing about arsenic as an impurity of phosphate of soda, although in the method of preparation described sulphuric acid is, of course, mentioned and under sulphuric acid a test is given for the presence of arsenical impurity. It would appear that the importance of the omission of any test for arsenic in phosphate of soda in the British Pharmacopœia was recognised previously to this prosecution, for a few days ago we received a specimen of the salt which is perfectly free from arsenic from Messrs. May and Baker of Garden Wharf, Church-road, Battersea, who have a stock of this article which they state they can supply without delay. It is a pity, we think, that if, as these druggists state, they knew of the important impurity they did not give greater and earlier publicity to the fact. In future, however, confidence may be felt that sodium phosphate will be supplied free from arsenic, for Mr. Plowden's ruling decides that a prosecution may properly be instituted under the Sale of Food and Drugs Act. Fines and costs were accordingly ordered to be paid by the defendants. The defendant druggists, of course, are entitled to the sympathy of the trade, but their annoyance should be considerably allayed by the fact that the publication of these proceedings has done an excellent service in the interests of public health, for vigorous steps are being taken both by wholesale and retail firms to provide in future nothing but absolutely arsenic-free phosphate of soda.

LEAD AND PHOSPHORUS POISONING.

IT is evident from the reply given by the Home Secretary to the questions raised by Sir Charles Dilke relating to the prevalence of lead-poisoning in the Potteries that no very substantial improvement has been effected amongst the work-people engaged in this dangerous trade. It is true that some diminution in the number of cases of lead-poisoning followed closely on the establishment of the new rules in 1898. According to the statement of Sir Charles Dilke, however, the diminution in 1899 was because the doctors now "suspended" from work people who had developed mild forms of lead-poisoning. This seems to us to imply an inadequate system of medical examination and the suggestion that a woman inspector should be appointed was made, a step which, however, Sir Matthew White Ridley declined to take. He admitted that lead-poisoning was a fearful thing in the Potteries and he promised that the Home Office would do everything that they possibly could to secure that the industry should be carried on in a manner as little harmful as possible to those engaged in it. The department hoped shortly to publish a new code of rules in accordance with the recommendations of Dr. Oliver and Dr. Thorpe, but there was to be no absolute prohibition of the use of raw lead. The Home Secretary did not think that much more could be done in regard to phosphorus, but he hoped that the cases of necrosis would continue to diminish as they had done in the past, one case only being reported during the past six months. Further, as a result of the public attention devoted to the subject, one large firm had abandoned the use of yellow phosphorus. The only really satisfactory issue of both these problems will be when it is found to be quite practicable to dispense altogether with both raw lead and yellow phosphorus.

THE SOUTH AFRICAN COMMISSION.

THE appointment of the two additional members to act upon the commission proceeding to South Africa to inquire into and report upon the arrangements for the care and treatment of the sick and wounded at the seat

of war has now been definitely settled and announced. The names of the new members are Sir David Richmond, ex-Lord Mayor of Glasgow, and Mr. Harrison, the general manager of the London and North-Western Railway. We do not think that a better choice could have been made. They will bring to the inquiry all the necessary business qualifications. We are especially glad that the traffic manager of a big line of railway has been selected, for we have strongly advocated this course, but we are of opinion that the constitution of the commission might have been further modified with advantage.

THE CONSTITUTION OF THE BRITISH MEDICAL ASSOCIATION.

AN extraordinary general meeting of the British Medical Association was held on July 18th at Exeter Hall to consider new articles of association providing, to sum up briefly, that the administration of the Association should remain in the hands of the Council. There was a fairly large attendance. The adoption of the new articles was proposed by Mr. Ward Cousins (President of the Association), supported by Dr. J. R. Thomson of Bournemouth (President of the Council). Neither of these gentlemen obtained the ear of the meeting. Mr. Victor Horsley spoke against the new articles, and after some words from Dr. F. M. Pope of Leicester and Dr. Lorimer Hart the business of the meeting terminated by the rejection of the Council's proposals for the adoption of the new articles.

AMONG the victims of the Peking massacre, concerning the occurrence of which there can no longer be more than the slenderest doubt, are three members of the medical profession, Dr. G. E. Morrison, Dr. Wordsworth Poole, and Miss Lillie E. V. Saville. Dr. Morrison, who was only 38 years of age, was an Australian by birth and received his medical education at Melbourne and Edinburgh. He was already a famous traveller and was the *Times* correspondent at Peking. Dr. Wordsworth Poole, who was also a young man, received his medical education at Cambridge, and had been principal medical officer at Zomba, Lake Nyassa, British Central Africa. He was staying at Peking with his wife. Miss Lillie Saville, M.D. Brux., received her medical education at the London School of Medicine for Women and had been a medical missionary in Peking for the past five years.

THE annual meeting of the subscribers to, and others interested in, the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Portland-terrace, Regent's-park, will be held at the hospital (near St. John's Wood-road station), on Wednesday, July 25th, at 3 P.M., when the Right Hon. the Earl of Hardwicke, President, will be in the chair.

H.R.H. THE PRINCESS OF WALES paid a visit to the London Hospital on Friday, July 13th, accompanied by her daughter Princess Victoria. After inspecting the extensions in the hospital, especially the new room for the light treatment of lupus, they had tea with the nurses.

AT the forthcoming International Medical Congress in Paris Dr. the Hon. Alan Herbert, physician to the Hertford British Hospital, Paris, will be presented with an address by the former and present medical officers of the hospital, numbering 20.

SIR HECTOR C. CAMERON, M.D. Glasg., President of the Faculty of Physicians and Surgeons of Glasgow, received his knighthood at the hands of the Queen at Windsor Castle on June 30th, as did also Sir George Hare Philipson, M.D. Cantab.

A TELEGRAM from Sir H. A. Blake, Governor of Hong-Kong, received at the Colonial Office on July 16th, stated that during the previous week 57 fresh cases of plague had occurred with 58 deaths.

DR. MARC ARMAND RUFFER, President of the Sanitary Maritime and Quarantine Board of Egypt, has received from His Majesty the Sultan of Turkey the Order and Insignia of the Medjidieh of the Second Class.

THE dignity of a Knighthood of the United Kingdom has been conferred upon the Hon. William Bisset Berry, M.D. Aberd., Q.C., Speaker of the House of Assembly of the Colony of the Cape of Good Hope.

MR. JOHN H. MORGAN, on resigning the position of senior surgeon to the Hospital for Sick Children, Great Ormond-street, has been unanimously elected consulting surgeon.

THE WAR IN SOUTH AFRICA.

OUR morning papers are full of wars and the rumours of wars at the present time and this country is realising the responsibilities of empire. The deplorable events which have occurred in China and the extent and formidable nature of the task which has to be undertaken in that country have tended to withdraw public attention for the time being from the war in South Africa, and to minimise and nearly exclude from consideration what under other circumstances would be regarded as most exciting events connected with the little campaign on the West Coast of Africa. Confining our attention, however, to South Africa we may say that the news from that seat of war was at the end of last week of a disappointing character. Although it cannot have any effect on the ultimate issue or undo what has been already accomplished there, the intelligence that the Boers had again carried out one of their successful surprises and had defeated a small British force and captured a number of British troops and taken some guns was very unpleasant reading. That the occurrence took place at this stage of the war and almost, as it were, under Lord Roberts's eyes, took the public by surprise and did not tend to decrease the sense of disappointment with which the news was received. If such occurrences have almost ceased to be regarded as surprising on account of their frequency, still it cannot be said that they have brought about that equanimity which might be expected to come from our being accustomed to them. De Wet and Botha are still active and enterprising and show remarkable skill in raiding, retreating, and eluding capture. Their tactics as guerilla chiefs seem remarkably good. Spies and disaffected persons no doubt abound in our camps and furnish them with early and reliable information as to all our movements.

Though there is not much news to hand at the moment of writing what there is is satisfactory. There is a great and increasing amount of activity on the part of the British forces. So far as we can gather the British troops, notwithstanding their hardships and fatiguing marches, are in excellent fettle and their health, as a whole, is good. There is, of course, a large amount of enteric fever, but the prevalence of the disease is believed to be diminishing and it is hoped that, what with the cold weather and a decreasing amount of fatigue and exposure on the part of the troops, it will continue to diminish.

We would call attention to the remarks of our Special Correspondent writing from Bloemfontein. As we have repeatedly urged the great difficulty in modern warfare—especially in a country like South Africa—is transport. We have always contended that a certain amount of transport should be independently set apart for the medical requirements of war and that it should never be diverted from this object except at the express order of the general in command and, where possible, in writing. This obtains in the American army, and there is or was, we believe, an Act of Congress to that effect.

The total losses reported from the beginning of the war up to the end of last week (exclusive of sick and wounded men now in British hospitals in South Africa) amount to 32,524. These are made up as follows according to the latest return issued from the War Office —

—	Officers.	Non-commissioned officers and men.
Killed in action	261	2,434
Died from wounds	72	637
Missing and prisoners (excluding those who have been recovered)	61	1,900
Prisoners who have died in captivity	1	84
Died from disease	139	4,563
Accidental deaths	—	70
Sent home as invalids	965	21,337
Total	1499	31,025

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

No. 3 Hospital Train returned on June 21st from Mafeking bringing to us the whole of the sick and wounded who had accumulated there, and as that was the third train-load we had received in six days we have had a busy week. In the last train-load there was another poor fellow—I think I mentioned to you some time ago that we had one similar unfortunate—who had lost both his eyes, and in the hospital at the present time there is also a man who only missed a similar accident by a quarter of an inch. The bridge of his nose was blown away by a transversely crossing shell, but most fortunately neither of his eyes was damaged. Both of the blind men show a most splendid spirit and pluck in their fearful adversity.

Lord Chesham, who has left again for the front, tells us that our field hospital was captured by Christian De Wet at Rhenoster and that it was made to move its camp to a neighbouring valley and told to lie low there until he could supply it with wounded. De Wet's agility and daring, which have resulted in so many surprises to our forces of late, enabled him, as you know, to swoop down upon the Derbyshire Militia just as they were detraining, and he kept his word to our field hospital by sending to them the 70 or 80 Derbyshires who were wounded before the rest capitulated. This commander is a thorn in the side of those of our troops who are placed along the railway to keep the lines of communication open, and one cannot help admiring his skilful and brave movements. We are told that he visited Lord Methuen and said that he would like to stop fighting, as he knew "the game was up," but that he could not do so until he received instructions.

I am glad to say that our invalid staff are all going on well. Greenfield and Parker are both convalescent and out of danger, and none of the other surgeons who have been "warded" have shown any symptoms of enteric fever. One-third of our orderlies are still on the sick list, but none of them are dangerously ill. Several of them have influenza—indeed, there is quite an epidemic of it—and the sudden invasion, by this fever, of patients whose temperature charts are being anxiously watched on account of the other illnesses often gives rise to anxiety. It is no uncommon thing for patients who have come down with wounds to develop enteric fever some days after admission, and similarly a few patients who have come in with other complaints have developed scarlet fever, for which we had to establish several weeks ago an isolation camp. One of our surgeons' dressers, Blathwayt, is among the recent recruits and it is a dull look-out for him to be condemned to six weeks' or seven weeks' seclusion "across the line." Now that influenza has made its appearance, imported from England we suppose, we have been provided with a third illness which has to be considered in investigating the cause of any sudden rise of temperature in a patient. The presence of scarlet fever in the camp has been a very great nuisance, for it has entailed a large increase in the heavy amount of disinfection which is called for in a camp of this size, but by means of stringent regulations and perpetually looking out for the earliest signs of the disease we have been able to limit it to a very few cases indeed. There are 16 cases in the isolation camp at the present time and there have never been more, but as five of them, in addition to Blathwayt, are members of the staff, and as their absence from duty is necessarily for the long period that I have mentioned, it is a serious blow from an administrative point of view.

We are all very much disappointed that the war does not crumple up more rapidly. We feel as if we had been away from home for two or three years. Somebody was suggesting the other day that instead of our going home when this war is over we should have to go on and establish a hospital in China, but I sincerely hope that this will not be the case, for we all feel that we have had quite enough of war for the present.

We have done all we possibly can to give an occasional day off to some of the less strong of the sisters, but the very fact that they have been so hard at work as to need it badly, has made it very difficult to arrange. One or two of them have changed places with a sister on a hospital train for a few days at a time, and this has secured them, if not a holiday, at least a change of work and a novel experience. Now, however, the 10 extra nursing sisters, whom the committee kindly despatched directly they received my application for them, have arrived, and they will be invaluable. Already they have enabled one or two of the sisters who have been working here without a break of any kind for three months to have "a day off." Many other sisters travelled with our 10 sisters from England, some for the hospital at Wynberg, who told ours that they were very jealous of their luck in being sent so much nearer to the front. It is very striking how deeply this wish to go to the front is embedded in everybody—until they have been there. The staff of each of the hospitals that I have come across is anxious to be pushed further forward under some hazy sort of impression that they want to be as near to the hub of the universe as possible. They have not a notion how their efforts to do good would be discounted at every turn by the great difficulty, or in some cases the impossibility, of getting the essentials for good work. The story told by those people coming down from the front is very different. Medical officers one after the other come here and say, "How fortunate your hospital is to have this lovely site and opportunities for quiet and good work unimpaired by the contamination of air and water and soil and the frightful difficulties of transport which hamper everybody up north." That exactly tallies with the experience which I derived from my journey up to Kroonstad a month ago. The difficulty of transport north of Bloemfontein is really so great that it dominates the whole situation. Colonel W. H. MacNamara, R.A.M.C., the principal medical officer of the lines of communication, was visiting us two or three days ago and told me that it has not yet been possible to get up to Kroonstad more than one-quarter of the hospitals, which are waiting packed in trucks, and should have been delivered there four weeks ago. Hospitals are, of course, useless when packed in trucks, and what is wanted to render them useful is not so much more hospitals packed in trucks as more steam engines and more water-supply along the line and less interruption of railway traffic at the vulnerable points of the line, such as bridges, &c. The hospital trains can get up and down all right; they always have efficient engines and now that many of the hospitals have been moved up-country to Norval's Pont, Springfontein, and Bloemfontein, and so on from Cape Town, these trains are more than equal to the demands made upon them to keep us well supplied with patients.

If this hospital could be picked up bodily and dropped down again without any interference with its work—that is an important point—at Norval's Pont it would not be a bad thing, for it would save about eight hours on the run of each hospital train and would place us in a region where eggs, milk, and butter are plentiful and good. Norval's Pont, however, was not in British hands when we pitched our camp, and there is nowhere else in South Africa that from our point of view is more suitable than Deelfontein. The weather now, though cold except when the sun is shining, is on the whole quite lovely—day after day of cloudless sky—and everything goes well with us.

I think that, knowing what you do of the amount of trouble that was expended in London on the thinking out of the equipment of this hospital, and knowing what I have written of the complete success which has crowned that work—for really we have everything that we want and nothing that we do not want—you will be amused to hear that somebody has been amusing himself by trying to make out that we came out unequipped for our work. The only instance that he can cite in support of this charge is that we had to borrow in our earliest days a few blankets. Plenty of blankets were sent by the committee from home and they got here by the time we were fit to declare a section of our hospital "ready," but before we were so ready Surgeon General W. D. Wilson, P.M.O., urgently requested us to place a few beds at his disposal at the earliest

possible date, and it was in order to comply with the request and so to help by every means in our power, even though our equipment was not yet complete, that we had to ask for a loan of some blankets—a loan that we have more than repaid already by the odds and ends of equipment which we have from time to time been called upon to contribute to others whose stock was exhausted or lost. In this way we have been able to lend a hand to many surgeons with battalions of Yeomanry as they went past us, and Lord Chesham only this week took back with him to his battalion at the front a supply of warm underclothing, Balaclava helmets, and so on, which he said were urgently needed, and which we had been placed in the position to afford by the kindness and energy of friends at home. Many people have been extremely generous in the way they have responded to the appeal in one of these letters some weeks ago for tobacco and sweets. Quite a large number of the officers here do not smoke, but almost all the men do, and it takes my wife between five and six hours every day, Sundays included, to accomplish her round of the hospital now that there are from 700 to 800 patients. She tells me that each week she distributes about 70 lb. of cake tobacco, 40 lb. of cut or packet tobacco, and 7000 cigarettes—that or more, besides many other "comforts." Idiosyncrasies and longings come out strong in such a large and varied collection of men. One poor fellow who died from cancer last Saturday had a special craving, sometimes very weird, almost every day he saw her. On the morning of the day he died he enjoyed some Madeira cake and a glass of port wine and soda-water. The day before nothing would content him but a dish of potatoes. For a few days before that he practically lived on oranges, which luckily we are able to get here now. One day he suddenly asked her for a stick of "Spanish." Liquorice was what he meant, so we wired to Cape Town and got some up in time for him thoroughly to enjoy munching a great stick and having some more dissolved in water so that everything he ate or drank for a day or two was flavoured with it.

Deelfontein, June 25th.

(FROM OUR SPECIAL CORRESPONDENT LATELY AT THE BASE.)

We are gradually getting the best of the epidemic, but still have a number of cases sent from outlying stations. At present there are roughly 1000 cases under treatment here in the various civil and military hospitals, but I trust that as the cold weather advances these numbers will materially decrease. No. 2 General Hospital went up to Pretoria yesterday and will be followed by the Irish Hospital in a few days. From all accounts there is not a great amount of sickness in Pretoria or Johannesburg, and it is at present doubtful, considering the very excellent hospitals that exist in these two towns whether it will be necessary to order up more general hospitals. One point has struck me during the war, and that is how well the enteric fever cases have done whilst under canvas; in fact, I think those treated in tents have certainly made more rapid recoveries than those treated in buildings. The cold is intense here mornings and evenings. There is a white frost on most days, but the sun has great power during the day, and given the absence of rain the climate at present ought to do wonders for the convalescents. I am glad to bear testimony to the excellent work performed by the men of the St. John Ambulance Corps who are out here; they have amply justified the good things said about them and they do their duty in an uncomplaining and willing manner and have been of the greatest assistance to us in our manifold duties. The lesson to be learnt for our next big campaign will, I trust, be impressed on the military authorities and the Treasury, and the system of starving the Royal Army Medical Corps during peace time with its attendant disadvantages rectified. The vital subject of transport, too, will require to be well looked into, as half of our difficulties at the present time are the result of deficient means of transporting the sick and wounded. In my own opinion, it is an absolute necessity in future wars that the medical transport should be in our own hands and should not be diverted from the purposes it is intended for. I hear to-day that there is a possibility of demands being made on our already impoverished ranks for duty at the Gold Coast and that volunteers for that work are likely to be called for. It is to be fervently hoped that the business will be of short duration, as the climate of West Africa can hardly be called salubrious, and the casualties are likely to be numerous at this season of the year.

Bloemfontein, June 23rd.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

The Four Medical Congresses: Press Arrangements and Festivities.

HENCEFORTH the medical press will not be able to complain of indifference on the part of the powers that be. Even the newly elected Municipal Council of Paris, which has shown a disposition to slight and to neglect what its predecessors had organised, is making an exception in favour of the International Congress of the Medical Press and has expressed the desire to give this congress an official reception at the Town Hall on Thursday, July 26th. As with the Guildhall or the Mansion House in London, so with the Hotel de Ville in Paris, foreigners are generally pleased to have an opportunity of visiting this historic municipal palace. But whatever lukewarmness the Nationalist majority of the Paris municipality may show, the Government is leaving no stone unturned to render the Exhibition and all the congresses connected therewith successful. Thus M. Millerand, Minister of Commerce, has promised to assist at the opening ceremony of the Medical Press Congress. This will take place at the Press Pavilion in the Exhibition grounds on Thursday afternoon, July 26th. On the following Saturday evening there is to be a banquet and entertainment in the picturesque reproduction of Old Paris which is one of the attractions of the Exhibition and it is anticipated that M. Waldeck Rousseau, the Prime Minister, will be present. On Friday evening, the 27th, there will be private receptions, and on Sunday, the 29th, excursions to Chantilly and Versailles will be organised. On Monday, the 30th, the Minister of the Interior will give a reception to the members of congresses present in Paris, and on Sunday, August 5th, the President of the Republic will give a garden party to the members of the Medical Press Congress and of the International Medical Congress which will then have assembled in Paris. Indeed, from July 23rd up to August 17th, may be qualified as devoted to medical men. It is unfortunate that the Medical Press Congress should meet during the last three days of the International Congress on Medical Ethics. With the exception of the opening ceremonies both congresses meet close together at the Faculty of Medicine and it is thought that the members of the medical press who are attending both congresses will be able to flit from one to the other according to the interest of the proceedings. This, in my opinion, is a serious mistake. It is the duty of the representatives of the medical press not to neglect questions affecting medical ethics, yet they are expected to meet at a congress of their own while the Congress on Medical Ethics is proceeding. But it is said that during the four days between July 28th when the Congress on Medical Ethics concludes and August 2nd when the General Medical Congress begins the members of the medical press will be usefully employed in organising the reporting of the Medical Congress. In view of such organisation a meeting of all the members of the medical press has been convoked at the Press Bureau of the Faculty of Medicine for Wednesday August 1st. But there has already been some organisation in this respect. For instance, all members who intend to read papers at the Medical Congress are requested to write in their own language a summary of 50 lines in length and to bring with them 200 printed copies of the same. The Press Bureau of the Faculty of Medicine, will then see that these slips are properly distributed and thus the authors of the papers, &c., will be relieved from all further trouble. Those members, however, who have neglected to do this will find at the Press Bureau an agency ready to have the 200 copies printed for them, and the cost will only amount to eight francs. This having been done, and as the press representatives are not convoked before the Wednesday, I cannot understand why the Medical Press Congress does not meet on the Monday and Tuesday instead of meeting at the end of the previous week when the Congress on Medical Ethics will also be holding its sittings.

Presidents of the Medical Press Congress.—Where to Put Up.

It is not necessary to describe anew the origin, object, and organisation of the International Congress of the Medical Press. The details will be found in my letter published in THE LANCET on May 5th (p. 1324). But I

should now add that Professor Virchow has taken the greatest interest in this congress, has promised to attend, and will preside over the sitting held on July 28th. Professor Baccelli of Genoa will preside on Friday afternoon and Professor Cornil will act as president for the French language Even at this, the eleventh hour, any member of the medical press will be welcome on payment of his entrance fee of £1 to the general secretary of the Congress, Dr. R. Blondel, 8, rue de Castellane, Paris. The temporary receipt given should be exchanged at any time on or after July 20th, at the offices of the French Association of the Medical Press, 93, Boulevard Saint Germain. These offices are not far from the Faculty of Medicine, and, indeed, it must be borne in mind that the Latin Quarter is the centre for all the four medical congresses. The sections will meet in the lecture halls of the Faculty of Medicine, of the Sorbonne, and of the great schools that have given to this quarter its name. Therefore, not only is there no necessity for the members of these congresses to put up in the expensive West-end of Paris or anywhere near to the Exhibition, but it would be inconvenient to do so. Rooms had better be sought on the south side of the river and as near to the lower part of the Boulevard St. Michel as possible. Excepting to attend one or two of the opening ceremonies or a banquet the members of the four medical congresses will have no occasion to go anywhere near the Exhibition, or the exclusive cosmopolitan part of Paris which has the Madeleine for its centre. Their work will be done in the University building, and therefore it will be more convenient, and many will find it more pleasant, to live in the University quarter.

The Opening Papers of the Medical Press Congress.

The two principal questions to be discussed at the International Congress of the Medical Press are the proposal to form an international association of the medical press, and, secondly, all that relates to the copyright of medical literary work. On the first of these questions Professor Posner of Berlin, Dr. Laborde of Paris, and Dr. Rubino of Naples have prepared reports. These papers are now in the press and will be printed in time for the opening of the Congress; but as I shall then have so much to say about the Congress on medical ethics, which will have held the greater part of its sittings, I had better profit by the present opportunity to give some account of these papers. Professor Posner commences by lamenting the present recrudescence of nationalism and individualism, each nation and each person seeking their own advancement and fiercely competing against their neighbours. But he claims that the ancient principle of professional confraternity has nevertheless survived among medical men, and he trusts that it may in time replace entirely the spirit of rivalry and competition. Yet there is no denying that the profession is in danger of being absorbed in the general current. It is to be hoped that the congress will inspire its members with a higher ideal than that of each striving solely for his individual advancement. As to-day the printed word is the greatest power extant for good or for evil, the medical press should strive not merely to spread scientific knowledge, but to study and defend the higher ethical interests of the profession. The learned professor then goes on to say:—"The conviction that this task can be more easily accomplished by the coöperation of all the forces than by mere individual efforts was first realised in France. The association of the medical press, founded in France, has become a prototype for analogous tendencies in other countries. The medical press of Germany and of Austria, which I have here the honour to represent, have followed the French example. If we examine the work of the medical press associations of Germany and Austria we can already congratulate these two bodies upon having succeeded in solving many problems submitted to them, though many of the ideal dreams on which these associations were based are not yet realised." To begin with the mere existence of such organisation has revealed a community of intellectual interests and a spirit of solidarity that had not been understood before. Friendships have been created, disputes avoided, and the better spirit engendered has been reflected in the columns of the medical journals much to the advantage of their readers. But practical advantages have ensued notably in regard to the reporting of medical congresses, though much remains to be done in this respect. Also by mutual understanding and common action the medical press could usefully influence legislation on all that relates to the public health. In this latter respect the German and Austrian associations of the medical press of those countries have barely realised the power they possess. The national organisations being thus so young and inexperienced it may well be questioned whether they are as yet strong enough to go a step further and to seek to establish an international organisation. Proceeding, Professor Posner says: "The extraordinary difficulties which the organisers of the Eleventh International Medical Congress held at Rome had to combat, and more especially those that were related to the organisation of the medical press, led my friend Marcel Baudouin and myself to elaborate a plan born out of our conversations. This plan was discussed at the banquet organised by the French medical journalists assembled at Rome." The plan was approved in spite of its difficulties and it will be the task of the present congress to elaborate the scheme. If the journalists would group themselves according to their language and then exchange their notes with those taken in other languages a much more accurate and complete review of the proceedings of international congresses could be obtained, also the work done in this collective manner would cost much less. Professor Posner then points out that as congresses depend for their success on the press, representatives of the press should have a voice in the organisation of such congresses. Such coöperation sometimes occurs, but it is not recognised as a principle and systematically regulated. Apart from the reporting of congresses there is need of an understanding as to what should be considered a legitimate quotation, the exchange of drawings or other illustrations, and the universal adoption of the same technical terms. Then something should be done to regulate the right of reply when controversies arise. But if it is necessary to go further than the mere expression of a pious wish, should there not be a representative executive power or committee the business of which it shall be to see that the rules accepted are uniformly applied? But no committee could exercise this power if it were not the representative of solid and durable organisations. Then there is the question of the relations to be established between the journalists of various nations. Professor Posner concludes by proposing that an International Association of the Medical Press shall be established having for its purpose to promote fraternal relations between the medical press of different nations, to represent and defend all common interests, to regulate the exchange of reports, newspapers, and news, and that an executive committee be elected to prepare a scheme on these lines.

The next report on this subject is by Dr. J. V. Laborde, President of the French Association of the Medical Press and editor of the *Tribune Médicale*. He commences by explaining that the whole trend of modern progress shows the necessity of bringing civilised nations closer together. Such "mutual penetration" is best assured by the press which conveys knowledge to each nation of what its neighbours have accomplished. When we consider how much the world has to benefit from the growth of biological and medical sciences, we need not insist on the necessity of facilitating the work of the medical press by which this knowledge is propagated. But, as science does not recognise political frontiers, its mouthpiece, the scientific press, should be internationally organised. This conception found public utterance at the Congress of Rome in 1894, and was eloquently expounded by Professor Posner of Berlin and Dr. Marcel Baudouin of Paris. Dr. Dobrozycki of Warsaw wanted to create, under the presidency of Dr. Laborde, a special section of the medical press at the International Medical Congresses. An international provisional committee was appointed. It met and drew up some proposals. Medical press associations were formed in Germany and Austria, but unfortunately no practical results were obtained when the International Medical Congress subsequently met at Moscow. Since then the German Association, and notably Professor Posner, has taken an active initiative, and this support has rendered the present Paris Congress possible. In this a great leader of modern science as well as of medical journalism, Professor Virchow, also lent efficient aid. Then came Dr. Selous of Philadelphia and Professor Alfredo of Naples. Dr. Laborde proceeded to give very elaborate rules for the future International Association of the Medical Press. These rules have a tendency, however, to put the cart before the horse; for instance, the members are to accept the regulations for the protection of medical literary property, other rules for the exchange of medical

journals, and the idea of publishing an international bulletin. This is going perhaps a little fast. But one proposal is very useful and practical—namely, that every medical journalist belonging to the International Association should have a card which will serve as an introduction in all countries. If the medical press organisations of each country would further take care that this card was recognised by their police, university, and hospital authorities, then a very great service would be rendered. It would take far too much space to analyse the numerous rules proposed and if they are to be adopted with any real knowledge of what is intended many days of very arduous discussion will be necessary. At the very onset a huge stumbling-block presents itself when the question is raised as to who shall be admitted as members of the association. Dr. Laborde says directors, editors, and general delegated secretaries. Are the special correspondents, the regular contributors, the writers on the staffs of the medical papers to be excluded, or are they considered as delegated secretaries, and if so, by whom delegated? Then, what is meant by directors? Are these the business and advertisement managers of papers or the proprietors of the papers? There are some so-called medical journals owned by wholesale druggists and published solely for the purpose of selling certain drugs. The motive of the association, we are told, will be the "moralisation of the profession"—a very good motive; but, in the same sentence we are informed that this end is to be obtained by protecting literary property. It is difficult to see the connexion. Is the druggist's property of an ingenious literary puff of a patent remedy to be protected by the united strength of an international association of medical journalists? No one could be more scandalised at such a suggestion than Dr. Laborde himself. Yet to avoid such contingencies the first step would be to define what constituted a medical journal and a medical journalist worthy of the name. At present and in different countries there are a good many sheets published that bear medical titles, deal with medical subjects, and yet are issued solely for the purpose of advertising the business of their proprietors. As the practice of medicine is a profession and not a trade such commercialism should be rigorously excluded. It would seem, however, as if the organisers of the Congress have failed to draw a sharp line between business and professional pursuits. In any case one of the papers which is to form a basis of discussion has for its author Monsieur F. Alcan, the Paris publisher, and surely publishing is a business and not a profession. Monsieur Alcan has written an interesting and appropriate paper. He is doubtless animated with the very best intentions, but he is neither a medical man nor a professional journalist. His paper deals with the reproduction of illustrations which, with existing photographic processes, is done on a very large scale and without the authors and owners of such illustrations being even aware that they have been reproduced. Then M. Alcan immediately speaks as a publisher might be expected to speak. He says that if the author of a medical treatise asks his publisher to send an artist or a photographer to his hospital or laboratory the drawing or photograph then made belongs undoubtedly to the publisher. But if the author supplies to the publisher a drawing or photograph the publisher is only the proprietor of the reproduction of the same. The author can give the same designs to some one else who may in his turn reproduce them. In both cases it should be the rule, says M. Alcan, to apply to the original publisher who should be willing to sell reproductions of the blocks for about half the original cost. The publisher would make a small profit and yet the purchaser would have to pay less than if he resorted to a photographic process. Then there is the question whether a publisher has the right to employ a design for other than the publication for which it was originally destined. Here M. Alcan speaks as a publisher and claims the right to do what he chooses with such blocks; but what would be the position of some eminent medical professor if some of the reproductions of his anatomical or other drawings fell into evil hands and were utilised to illustrate some quack or pornographic publication? It is most desirable that publishers should meet authors and discuss amicably their mutual interests, but to jumble both up together in one single congress can only lead to confusion. Each side must separately formulate their desiderata, then and then only may they meet to effect a common understanding or compromise. M. Alcan goes on to explain that in France it is not yet settled whether photographs come under the laws affecting literary and artistic property or those governing industrial property. With regard to portraits the photographer may give the publisher the right of reproducing the portrait if the person photographed consents. The publisher may have to pay for this permission. On the other hand, the person photographed may give his photograph to anyone else and authorise the latter to reproduce it. Thus the publisher's copyright becomes valueless. Doubtless this is important from the publisher's point of view, but it is less certain that eminent medical celebrities when giving their photographs to some friend or relative will take care first to obtain a pledge that the portrait shall never in any way be reproduced.

On this question of copyright there is another and lengthy report by M. de Maurans, editor of the *Semaine Médicale* and by two eminent barristers well known for their special knowledge of the subject—namely, M. M. Pouillet and M. G. Rocher. The author of a medical book has the same rights, they remark, as the author of a novel or any other book; but what is the position of the author of an idea or a discovery and of a clinical or other lecture delivered concerning the same? They continue: "The professor must give all his science to his pupils. The latter may take notes, even shorthand notes, learn what they have heard off by heart, and deduce from it the utmost possible personal instruction; but their rights go no farther than this. They cannot repeat the lecture or publish it. The professor's lecture is like an open book: the pupils may learn from it but must not attempt to make a pecuniary profit out of it." This principle was established by a verdict rendered in a Paris court on August 27th, 1828, and confirmed by another verdict on March 2nd, 1841. For the defence it was urged that as the State paid the professors their lectures became public property. The answer was that the State paid the professors to teach and not to provide the material for a book. In conformity with this judgment the reporters maintain that medical journals have not the right to reproduce clinical, university, or hospital lectures unless authorised to do so by the lecturer. Further, in giving such authorisation the lecturer should have the right to impose any conditions he may choose. This condition of affairs, I should imagine, will not be unanimously approved. The natural eagerness to create and to protect property should not efface from sight the fact that what is done publicly should be liable to public criticism; and how can lectures be criticised if they cannot be quoted. But it might with justice be urged that lecturers should be offered an opportunity of correcting the proofs of the reports of what they had said, and that as a matter of courtesy a copy of the paper in which they are mentioned might be presented to them. The reporters conclude by a humorous warning to medical authors and lecturers to be careful not so to describe their cases as to enable the personality of their patients to be recognised. The novelist Charette, to avoid trouble of this description, declared that he had selected for his heroes the names of bankrupts or of criminals who had been guillotined. But the dead leave relations who are apt to take offence. Thus a few years ago the author of a medical work on degeneration and criminality was prosecuted because some of his cases were recognised and one of them was precisely that of a man who had been guillotined. A descendant of this culprit went to law on the subject, and the tribunal ordered that the incriminating passage should be expunged from the book.

Dr. Marcel Baudouin has a paper on the Property of the Idea and the Form of the Idea in Scientific Journalism. Dr. Baudouin is Director of the International Institute of Scientific Bibliography and member of the Superior Commission of the Press at the Exhibition of 1900. He argues that an idea is a property and should be protected as such. But as yet the law has only attempted to protect the materialisation of ideas. For this it would be necessary to have some method of registering, nationally and internationally, scientific ideas. The International Institute of Bibliography, which registers day by day the intellectual productions of the entire world, might serve as a basis for such an organisation. Even now we are able to say who was the first person to give a written or drawn expression of an idea and to find this out promptly by the system of registering now adopted—*Répertoires idéologiques chiffrés*. By these methods of registering it would not be so difficult to ascertain what really does constitute a new idea. Dealing at great length with the existing copyright laws, Dr. Baudouin does not agree completely with the papers of

M. Pouillet, M. Rochet, and M. Alcan. He is not in favour of severe checks to prevent the reproduction of lectures, newspaper articles, speeches, &c., but he is anxious to protect a genuinely new idea. To check the reproduction of scientific drawings is to check the spread of education, excepting when such check is necessary so as to prevent disloyal competition. What needs special protection is not so much the literary construction of phrases to explain an idea or an artistic illustration, but the idea itself, however roughly expressed.

Several papers will be read on the constitution of the medical press in different countries. M. Lévy, editor of the *Revue Illustrée de Polytechnique Médicale*, will read a paper on the use of a pseudonym preceded by the term "Dr." in the writing of "puffs." M. de Maurcous has a paper on the affiliation of associations of the general or political press. There are to be papers on medical journals that are gratuitously distributed and have no *bonâ-fide* sale and on gratuitous publicity and its dangers. Dr. Blondel has a paper on the reports published of meetings of learned societies and the effects of such publicity on special reviews or magazines. M. Jayle, sub-editor of the *Presse Médicale*, will deal with personal controversies and the right of reply. Professor Bossi of Genoa will speak on the relation between medical journals that deal with sanitary questions and the general press. Professor Richet, editor of the *Revue Scientifique*, will treat the question of agreeing to employ an international decimal dictionary for the translation of figures, measures, &c., and another paper suggests a common agreement as to the spelling to be adopted in translating Slav names into the Latin alphabet; then there are some technical papers on the binding of journals or the wrapper problem, the reproduction of coloured illustrations, and the use of the phonograph and the kinematograph in reporting.

So far, therefore, as technicalities are concerned there is enough and more than enough to talk about, but it is in respect to organisation, the principle and basis of organisation, that the programme seems weak. However, this is but a first attempt. A great step forward will have been accomplished if a sort of professional feeling is engendered between medical journalists leading to the ultimate adoption of one ethical code for their moral guidance.

Paris, July 16th.

BRITISH MEDICAL GUILDS AND THE INTERNATIONAL CONGRESS ON MEDICAL ETHICS.

ON Monday, July 23rd, the First International Congress on Medical Ethics or Deontology will hold its first sitting at the Press Pavilion on the Exhibition grounds and will meet for the rest of the week at the Paris Faculty of Medicine. We regret to hear that the British medical unions, guilds, and kindred organisations have not responded as fully to the widely distributed invitation as we had every reason to expect. The object and utility of an international congress dealing with the economic interests and position of the medical profession seem to have been better appreciated on the continent. Of course, the French members will be the most numerous as the Congress meets in Paris. The nation which so far and after France sends the greatest number of members is Italy. Then come Switzerland, Germany, the United States of America, Belgium, Spain, Russia, Denmark, and Great Britain is only ninth on the list, followed closely by Austria, Roumania, and Holland. The nations sending but three or four delegates are Portugal, Egypt, Turkey, Greece, Brazil, Venezuela, Sweden, Norway, and Canada, while Uruguay, Peru, Cuba, Japan, and Mexico have each one delegate only. Counting Canada this makes 27 different countries that will be represented and the list is not yet complete. Considering the importance of Great Britain as a nation, the political freedom to form organisations which we have long enjoyed, and our experience in the art of self-government, the representatives from Great Britain should have been more numerous and have taken a more active part in the preparation of papers or reports. Some English papers, as our readers are aware, have been announced, but these are not as numerous as might reasonably have been expected. Still, there is yet time to augment our list of members, and in any case a greater show of sympathy might be made. Of course, we can well understand that the medical unions that exist are of but recent creation and do not in most cases dispose of sufficient funds to pay the expenses of sending special representatives to Paris. But there are many members of these medical organisations who propose to visit the Paris Exhibition at their own expense, and they might have arranged to do so at the time when the Congress was being held so as to put in an appearance on behalf of their societies. Those practitioners who do not belong to any such organisations will also be welcome if they sympathise with the object of the Congress, and we hold at their disposal circulars of invitation if they will apply to us for them. The movement—namely, the forming of medical unions for the defence of the economical and ethical interests of the medical profession—is now so widespread that a proposal to establish an international federation of such unions has already been forwarded to the organisers of the Congress from several different quarters. It is also proposed that these congresses should be held at regular intervals and invitations for the next Congress on Medical Ethics have already been received from Brussels, Liège, Rome, Vienna, and St. Petersburg. Further, and so that the work of the Congress should be widely known, the General Association of the French Medical Press has made arrangements to act as secretary or agent of all the members of the Congress. The Press Bureau of this association will undertake to have 150 copies made of summaries of speeches, to pay the postage, and forward these to 150 different papers for 8*s*. if they do not exceed 15 lines and 15*s*. if they amount to 50 or more lines. The charge made, it will be seen, barely covers postage and stationery; it is a work of propaganda, not a commercial undertaking.

Finally, we would urge that those medical unions, guilds, &c., which are absolutely unable to secure the presence of representatives might, nevertheless, authorise their president or secretary to enrol himself as a member of the Congress. This implies the filling up of the form of application attached to the circulars of invitation and the forwarding of the subscription of 12*s*. to M. Masson, treasurer, 120, Boulevard St. Germain. This might be followed by a letter of apology for non-attendance, an expression of approval, and any statement which it might be thought useful to make. The name of the society would then appear in all the documents and in due course the society would receive the report of the proceedings, which will be a volume containing much useful information. For the modest outlay of 12*s*. the various societies that are not sending delegates would thus, nevertheless, contribute materially and morally to ensure the success of their colleagues of all nations who are struggling to promote the same cause that they are defending in England.

The programme and printed reports are now ready, and these, together with the card of membership which gives the right of free admittance to the Exhibition and to the sittings of the Congress, can be obtained on applying at the Masson Library, 120, Boulevard St. Germain. We are also asked to notify that the General Secretary of the Congress has changed his address and communications for him should now be addressed to Dr. Jules Glover, 23, rue de la Bienfaisance, Paris.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

QUARTERLY MEETING.

A QUARTERLY meeting of the Council was held on July 12th, the President, Sir William Mac Cormac, Bart., K.C.V.O., being in the chair.

The PRESIDENT reported the re-election as members of the Council of Mr. John Tweedy and Mr. Alfred Cooper and the election of Mr. Ward Cousins and Mr. Alfred Pearce Gould.

Mr. Tweedy, Mr. Cooper, Mr. Ward Cousins, and Mr. Pearce Gould were introduced, made declarations in the terms of the oath as prescribed by the Charter of 1800, and took their seats as Members of the Council.

It was resolved that the salary of the conservator of the museum should be increased.

It was resolved to print 250 additional copies of the first

volume of the second edition of the "Physiological Catalogue."

It was resolved that the deputation to H.R.H. the Prince of Wales should consist of the President, the Vice-President, Mr. Bryant, as senior member of the Council, the Secretary, and the Assistant Secretary.

The Council then proceeded to the election of the Most Hon. the Marquess of Salisbury, K.G., and the Right Hon. the Earl of Rosebery, K.G., K.T., as Honorary Fellows of the College.

The alterations in the by-laws relating to the Fellowship were signed by the members of the Council who were present and they were sent to the Secretary of State for Home Affairs for approval.

The PRESIDENT reported that on the day appointed for a meeting of Fellows under Section XXIII. of the regulations of the Council the required quorum was not obtained, 20 Fellows only, including three members of Council, having attended, and accordingly no meeting had been held.

A letter was read from Mr. THOMAS BRYANT, reporting the proceedings of the General Medical Council at their late session, and the thanks of the Council were given to Mr. Bryant for his services as the representative of the College on the General Medical Council.

A report was read from Mr. MORTON SMALE, member of the Board of Examiners in Dental Surgery, upon Dental Education in the United States of America. Mr. Morton Smale was thanked for his report, which was referred to the Dental Board.

ELECTION OF PRESIDENT AND OFFICERS.

Sir William Mac Cormac was unanimously re-elected President for the fifth time, and Mr. J. Langton and Mr. Henry Morris were appointed Vice-Presidents. Mr. Charles Stewart, Mr. Percy Furnivall, and Professor Christopher Addison were elected Hunterian Professors for the ensuing year. Dr. T. Grigor Brodie was elected Arris and Gale Lecturer and Mr. Walter Edmunds was elected Erasmus Wilson Lecturer. Mr. F. Canton was re-elected, and Mr. Storer Bennett was elected, a member of the Board of Examiners in Dental Surgery.

THE HONORARY FELLOWS.

The following three distinguished Honorary Fellows have already been made:—

H.R.H. The PRINCE OF WALES, K.G., Elected June 14th, 1900.
The Most Hon. the MARQUIS OF SALISBURY, K.G. } Elected July 12th,
The Right Hon. the EARL OF ROSEBERY, K.G., K.T. } 1900.

The following is the list of Honorary Fellows of the Royal College of Surgeons of England who will be elected on Thursday next subject to their being present to receive the diploma:—

Albert, Eduard Professor of Clinical Surgery, University of Vienna.
Ball, Charles Bent, M.D., M.Ch., Regius Professor of Surgery, University of Dublin.
Bassini, Edoardo, Professor of Clinical Surgery, Royal University of Padua.
Bennett, Edward Hallaran, M.D., M.Ch., Professor of Surgery, Trinity College, Dublin.
Berg, John Wilhelm, Professor of Surgery, Royal Caroline Institute of Medicine and Surgery, Stockholm.
Von Bergmann, S. Exc. Professor Dr. Ernst, Geh. Med. Rath, Berlin.
Bloch, Oscar, Professor of Surgery, University of Copenhagen.
Bottini, Enrico, Professor of Clinical Surgery, Royal University of Pavia.
Cameron, I. H., Professor of Clinical Surgery, University of Toronto.
Cardenal Fernandez, Dr. Salvador, Vice-President Royal Academy of Medicine and Surgery, Barcelona.
D'Antona, Antonino, Professor of Surgery, Royal University of Naples.
Durante, Francesco, Professor of Clinical Surgery, Royal University of Rome.
Von Esmarch, S. Exc. Professor Dr. Friedrich, Wirkl. Geh. Rath, Kiel.
Halsted, William Stewart, M.D., Professor of Surgery, Johns Hopkins University, Baltimore.
Hingston, Hon. Sir William Hales, M.D., LL.D., D.C.L., Professor of Clinical Surgery, University of Laval.
Jameson, Surgeon-General James, C.B., M.D., LL.D., Director-General Army Medical Service.
Keen, William Williams, M.D., LL.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia.
Kocher, Theodor, Professor of Surgery, University of Bern.
König, Professor Dr. Franz, Geh. Med. Rath, Berlin.
Küster, Professor Dr. Ernst Georg Ferdinand, Geh. Med. Rath, Marburg.
Lambotte, Elie, Brussels.
Lannelongue, Odilon Marc, Professor of Surgical Pathology, Faculty of Medicine of Paris.
Lennander, Karl Gustaf, M.D., Professor of Surgery and Obstetrics, University of Upsala.
Macewen, William, M.D., LL.D., F.R.S., Regius Professor of Surgery, University of Glasgow.
MacLeod, Colonel Kenneth, M.D., LL.D., I.M.S., Professor of Clinical and Military Medicine, Army Medical School, Netley.
Nicolaysen, Julius, Professor of Surgery, Royal University of Christiania.
Norbury, Sir Henry Frederick, K.C.B., Director-General, Medical Department of the Royal Navy.
Ollier, Leopold, Professor of Clinical Surgery, University of Lyons.
Pachoutine, Victor, President, Imperial Military Academy of Medicine, St. Petersburg.
Pozzi, Samuel, Professor, Faculty of Medicine of Paris.
Raye, Colonel Daniel Charles O'Connell, M.D., Indian Medical Service.
Roddick, Thomas G., M.D., C.M., Professor of Surgery, McGill University, Montreal.
Rubio y Gali, Federico, Member of the Royal Academy of Medicine of Madrid.
Sklifossovsky, Nicolas Wassilievitch, Director and Emeritus Professor, Imperial Clinical Institute of the Grand Duchess Helena Pavlovna, St. Petersburg.
Tillaux, Paul, Professor of Clinical Surgery, Faculty of Medicine of Paris.
Veliaminoff, Nicolas, Professor of Surgery, Imperial Military Academy of Medicine, St. Petersburg.
Warren, John Collins, M.D., Professor of Surgery, Harvard University.
Weir, Robert Fulton, M.D., Professor of Clinical Surgery, Columbia University, New York.

A deputation will attend at Marlborough House on July 24th to present the Diploma of Honorary Fellowship to H.R.H. the Prince of Wales.

The Marquis of Salisbury and the Earl of Rosebery and all the other Honorary Fellows have expressed their intention of attending the meeting to be held on July 26th, at 3 P.M., in the theatre of the University of London, Burlington-gardens, to receive their diplomas.

COMMEMORATION DINNER OF THE EPIDEMIOLOGICAL SOCIETY.

A HIGHLY successful dinner of this society was held at the Grand Hotel, Trafalgar-square, on Friday, July 13th, to commemorate the fiftieth anniversary of the foundation of the society. The President, Dr. FRANKLIN PARSONS, occupied the chair, and among the guests who accepted the hospitality of the society were Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., honorary member of the society, Sir William Broadbent, Bart., F.R.S., Sir Douglas Powell, Bart., Sir Henry Norbury, K.C.B. (Director-General of the Royal Navy Medical Department), Sir Archibald Geikie, F.R.S. (Director-General of the Geological Survey), the President of the Royal College of Physicians (Dr. W. S. Church), the Parliamentary Secretary of the Local Government Board (Mr. T. W. Russell, M.P.), the Director-General of the Army Medical Department (Surgeon-General Jameson, C.B.), the Permanent Secretary of the Local Government Board (Mr. S. B. Provis, C.B.), the Legal Adviser to the Post Office (Sir Robert Hunter), the President of the Medical Society of London (Dr. Frederick Roberts), Dr. Farquharson, M.P., Mr. Harry Farnall, C.M.G. (of the Foreign Office), Professor Macfadyen (Director of the Jenner Institute), Professor Sims Woodhead, Sir James Crichton Browne, K.C.B., F.R.S., Professor Haldane, F.R.S., Dr. Dawson Williams, Mr. Fryer (of the Board of Trade), Dr. Hector Mackenzie, Mr. W. F. Blake, L.C.C., Dr. F. J. Allan, and many others, while among the members of the society present were Dr. W. A. Bond, Mr. R. M. Bruce, Dr. G. S. Buchanan, Dr. Bulstrode (honorary secretary), Dr. F. F. Caiger, Dr. Childs, Professor Corfield, Dr. J. W. H. Eyre, Dr. Wilfred Fletcher, Dr. E. W. Goodall, Dr. Russell Harris, Dr. Bruce Low, Dr. Spencer Low, Dr. J. MacCombie, Dr. Patrick Manson, C.M.G., F.R.S., Mr. Shirley Murphy, Dr. Newsholme, Colonel Lane Notter, R.A.M.C., Mr. W. C. C. Pakes, Dr. J. Frank Payne, Dr. R. Reece, Dr. J. Robertson, Mr. W. N. Shaw, F.R.S. (Secretary of the Meteorological Council), Dr. Steegmann, Mr. Hugh Stott, Dr. R. D. R. Sweeting (treasurer of the society), Dr. J. F. J. Sykes, Dr. Theodore Thomson, and Dr. B. A. Whitelegge. Each guest was presented with a little commemoration volume giving a short history of the foundation of the society and a list of its founders, presidents, treasurers, and honorary secretaries since the foundation.

The toast of "The Queen" having been proposed by the CHAIRMAN and duly honoured by the singing of the National Anthem by an admirable quartette, Sir ARCHIBALD GEIKIE proposed "The Navy and Army

and Auxiliary Forces" which was responded to by Sir HENRY NORBURY, K.C.B., and Surgeon-General JAMESON, C.B. The latter in the course of a very vigorous speech, which was listened to with great attention, discussed somewhat in detail the allegations directed against the hospital and ambulance arrangements in South Africa. The Royal Army Medical Corps have in the past not been without honour and appreciation, but now a change seemed to have come over the spirit of their dreams and criticism was in certain quarters rife. The service had still, however, its friends; and the support of such men as Sir William Mac Cormac, Mr. Treves, and Sir Redvers Buller, none of whom would give praise where it was undeserved, would have to be reckoned with. Lord Roberts, too, whose sympathy with the soldiers was a household word, would not have expressed his satisfaction at the arrangements had they been, as is alleged by some, insufficient in character and extent. There was also one other opinion that he (Dr. Jameson) valued most highly, and it was that of the German military medical attachés. They were with the British medical staff and had afforded them valuable assistance on many occasions. When the Germans returned to England he asked them if they had any improvements to suggest and they answered, "We have nothing to suggest." On the other hand, what were the qualifications of the men who criticised them? He (Dr. Jameson) had read the criticisms in question when he was on his way to Ireland; he thought they were much exaggerated and he determined, like Mr. Rhodes, to come back to London and "face the music." As he drove back through the streets of London the placards referring to "hospital scandals" and "atrocities" raised a question in his mind whether they were not working up to a prominent position in Madame Tussaud's collection. His duty was to provide beds for 10 per cent. of the troops and this had been done, and a *personnel* of over 8000 men and women had been provided for these beds. So liberal, indeed, had been the allowances that on several occasions he had been asked to furnish no further equipment, and on Thursday last he received a telegram from South Africa in these words: "Please do not send any more base hospitals." It was well known to the medical officers that exigencies might arise with which no service in the world could deal, and had the outbreak of enteric fever which was here the subject of consideration occurred in London itself the hospitals of the metropolis would not have been able to cope with the situation. The commission which had been appointed would bring out the truth, and the Army Medical Department asked for nothing other than this.

Sir JOSEPH FAYRER proposed the toast of "The Founders of the Epidemiological Society," and in a most interesting speech traced the history of the society's foundation. He referred to the circumstances which obtained in England just prior to 1850 and to the fact that the society, arriving, as it were, at the psychological moment, carried all before it. Amongst its founders were numbered the leaders of science and medicine of the day and the work which the society did was so much appreciated in Europe that Hirsch in 1860 dedicated the first edition of his now classical "Historical and Geographical Pathology" to it. Sir Joseph Fayrer referred to the valuable work performed by the several committees of the society and to the influence which the society had had in directing the Legislature with regard to the control of small-pox by means of vaccination. A reference to the list of presidents would at once convince the reader that in this particular the society, which might justly be termed "the father of preventive medicine societies," had been exceptionally fortunate. As regards the jubilee it had been determined that the event might be well and usefully marked by publishing an Index of the valuable papers which have appeared in the Transactions. Sir Joseph Fayrer paid a fitting tribute to the valuable contributions which had been made to the science of epidemiology by the writings of the outgoing President, Dr. Franklin Parsons, and he predicted that under the guidance of the President-elect, Dr. Patrick Manson, whose work in tropical diseases had been recently appreciated by the Royal Society, the society would enter upon the second 50 years' work with unabated vigour and utility. Of the names which appeared upon the historic roll of the founders there were but two survivors, Sir John Simon, K.C.B., and Sir Edward Sieveking, and age alone prevented their attendance at the feast. He proposed, however, that the names of these gentlemen should be coupled with the toast and that a telegram be despatched to each of them conveying to them a hearty greeting, a suggestion which was most cordially accepted and acted upon.

The toast of "The Public Health Service" was proposed by Dr. FARQUHARSON, M.P., and responded to by Mr. T. W. RUSSELL, M.P.

Dr. PATRICK MANSON proposed the toast of "The Visitors," and coupled with it the names of the President of the Royal College of Physicians and Sir James Crichton Browne.

Dr. CHURCH, who met with a very cordial reception, was unable to pass over in silence the fact that he had consented to take a place in the commission which was to proceed to South Africa to investigate the provisions made for the sick and wounded. He felt when Lord Lansdowne sent for him that unless he (Dr. Church) did what an Englishman never did—i.e., shirked his duty—he could not refuse to take part in the commission in question. He trusted, however, that all who knew him felt that he would enter upon the arduous and responsible duty which had devolved upon him with perfect impartiality. He could not but have a high regard for the Army Medical Service, but he trusted that this fact would in no sense preclude him from approaching the inquiry with a mind entirely free from bias. Dr. Church referred in a highly appreciative manner to the admirable work performed by the Epidemiological Society in elucidating the causes of epidemic diseases, and expressed regret that he had not himself been actively engaged in the work of the society. He trusted, however, that in spite of his having no special knowledge in this sense he was not without a certain amount of that commodity which the House of Commons were unwilling to allow that the medical profession possessed—i.e., common sense—and he hoped that by making use of that faculty he might be able to be of some use to his country.

Sir WILLIAM BROADBENT proposed the toast of "The President and Officers of the Society," which was responded to by Dr. PARSONS and Dr. BULSTRODE. The society had, Dr. Parsons stated, received many letters of regret and appreciation from different parts of the world and one which had just arrived from Russia ran as follows: "The young Russian Society of Preventive Medicine greets the venerable Epidemiological Society and heartily wishes it further flourishment.—President, Prince Petr of Oldenburg; Member of Council, Dr. Leo Berthenson; Secretary, Dr. Vonitch." Dr. Parsons referred in appreciative terms to the manner in which his work as President had been supported by the efforts of the treasurer and honorary secretaries, one of whom, Dr. Washbourn, was at that moment serving his country in South Africa. The Index to which Sir Joseph Fayrer had referred was, he added, compiled by Mrs. H. T. Bulstrode.

ASYLUM REPORTS.

The Nottingham City Asylum, Mapperley Hill (Annual Report for 1899).—The average number of patients resident during the year was 659 and comprised 311 males and 348 females. There were 22 private patients in residence during the year, eight of them being males and 14 females. 152 patients were admitted during the year, 74 being males and 78 females. The admission rate was the lowest since 1891 and was 16 below the average for the past five years. Among the admissions there was an unusual number of senile cases, and many of the patients were in a weak and emaciated physical condition. Mr. Evan Powell, the medical superintendent, states in his report that the cases admitted were on the whole of an unfavourable character as regards hope of recovery. As to causes there was nothing unusual noticed; drink and hereditary influences headed the list. There were 62 patients discharged as recovered during the year, 32 being males and 30 being females, a total of 9·4 per cent. of the average number resident. Four female chronic patients were removed to the workhouse to make room for acute cases. The number of deaths during the year numbered 59, as against 53 in the previous year, or 9 per cent. of the average number resident. Of the deaths three were due to cardiac valvular disease, three to senile decay, three to epilepsy, four to bronchitis, four to cerebral atrophy, seven to phthisis, and 19 to general paralysis of the insane. "There is still much overcrowding in the female division, and as a consequence of this erysipelas has made its appearance on more than one occasion.

Besides the danger to the health of the patients the congested state of the wards renders it very difficult to treat the cases properly." The report states that the new female wing of the asylum will probably be ready for occupation in midsummer, 1900, when the overcrowding will be relieved temporarily, but the further steps to be taken for providing additional accommodation will be a matter for very serious consideration. Two of the sanitary blocks on the female side have been enlarged in a satisfactory manner. A female patient who was admitted in February gave birth to a full-term male child in August. The child was removed by the father, but the mother is still a patient in the asylum and is not likely to recover. The only casualty of a serious nature occurred in the female side, where a patient who was accidentally pushed down by another sustained a fracture of the neck of the femur. Four male and three female patients made their escape, but all were retaken after short periods of absence except two of the men, who succeeded in remaining away for the statutory 14 days when they were considered as discharged. The Lunacy Commissioners in their report state that a small isolation block should be provided for infec tious cases. "Had it not been that a patient recently attacked by scarlet fever was a small idiot child and could therefore be treated in the public fever hospital the present isolation hospital would have had to be emptied of the patients now residing there and much inconvenience and discomfort would have arisen." The Commissioners have had one grievance brought to their notice which they think is a substantial one, and that is "that the patients are taken to the Guildhall to be seen by the justices before they are sent to the asylum, as if they were criminals, and not visited in their own homes as sick persons would expect to be." The Commissioners advert to the insufficiency of the staff in No. 8 ward, where there were 45 patients, of whom 11 were in bed and eight were actively suicidal, in charge of four nurses. Post-mortem examinations were made in 88 per cent. of the deaths, and bed-sores were found to be present in 7 per cent. The case-books and other medical records are carefully kept and some pathological work is done, the committee having made the necessary additions to the appliances for the latter purpose.

Leicester Borough Asylum, West Humberstone (Annual Report for 1899).—The average population of the asylum was 561 patients—viz., 262 males and 299 females. The admissions during the year were 118, and comprised 49 males and 69 females. Dr. J. E. Montague Finch, the medical superintendent, states in his report that of the 118 admissions 27 had previously been patients in the asylum. "Many of the cases were in extremely feeble health when admitted. Two died on the day of admission and one on the third day. Many were bedridden and two were over 80 years." The chief cause of insanity among the patients admitted was hereditary tendency, which was a factor in 42 cases. Among the other causes were the following: intemperance in drink nine causes, mental worry and domestic trouble 10 cases, and senile brain decay five cases. The cases discharged as cured during the year amounted to 57—viz., 25 males and 32 females—a total of 10·1 per cent of the average number resident. The number of deaths during the year amounted to 30—viz., 19 males and 11 females, or 5 3 per cent. of the average number resident. Of the deaths two were due to cancer, two to phthisis, three to renal diseases, three to senile decay, five to cardiac disease, and nine to general paralysis of the insane. One death—viz., that of an elderly male patient—was due to suicide by cutting the throat. "Three inquests were held upon patients who died during the year. In two of these cases the patients were in a moribund condition when admitted." One of them died within an hour of admission from pulmonary apoplexy, and the other died within 12 hours of admission in an advanced stage of phthisis. The third inquest was on a case of suicide which occurred while the patient was out upon trial in charge of his friends after an absence from the asylum of some weeks. The general health of the asylum has been fairly good, and no disease of an epidemic character has occurred with the exception of a few sporadic cases of influenza. The only accident of a serious character was a fracture of the radius sustained by a patient during a struggle with another. A male patient escaped while at work on the farm and was not recaptured. On July 20th the memorial stone of the asylum extension was laid by Mr. George Clifton, the chairman of the committee, who at the time was also Mayor of Leicester. The main structure is now approaching completion, but there still remains a large amount of woodwork and other fittings to be done. "In the meantime it becomes more and more difficult to find accommodation for the increasing number of patients. ..... As at present determined, the contemplated additional blocks for 100 male patients and 30 female patients are not to be proceeded with, but it is more than probable that these will be required before many years have elapsed." The changes in the staff of attendants have been numerous, more especially towards the end of the year, when several reservists had to join the army. In these cases it was arranged by the committee that the dependent relatives should have an amount equal to half-pay during the absence of the attendant, and that he should be reinstated upon his return to civil life. The Lunacy Commissioners in their report state that they hope the committee will consider the propriety of erecting a new and detached building in preference to enlarging the present building for patients. An adequate staff continues to be maintained, giving one attendant for every 11 male patients and a nurse for every 10 female patients. The case books and medical records are stated to be well kept.

East Sussex County Asylum, Haywards Heath (Annua Report for 1899).—The average number of patients resident during the year was 921, and comprised 388 males and 533 females. The number of admissions during the year amounted to 271, including 119 males and 152 females. Of these 44—viz., 19 males and 25 females—were re-admissions. Dr. C. E. Saunders, the medical superintendent, states in his report that the admissions show an actual increase of four males and 24 females on those of the previous year. As regards the expectancy of recovery 51 out of 109 males and 68 out of 150 females are tabulated as bad or hopeless. Of the male patients admitted 35 are regarded as actively suicidal and of the females 54 are so included. The patients discharged as recovered during the year amounted to 85 and comprised 38 males and 47 females, a total of 9·2 per cent. of the average number resident. The deaths during the year amounted to 90—viz., 44 males and 46 females—a total of 9·7 per cent. as calculated on the same basis. Of the deaths three were due to renal disease, four to pneumonia, two to broncho-pneumonia, three to bronchitis, five to phthisis, six to senile decay, seven to cardiac disease, 18 to organic brain disease (cerebral softening, atrophy, or tumour), and 18 to general paralysis of the insane. In one instance only was a coroner's inquest held, viz., in a case of death due to peritonitis caused by the perforation of a gall-stone. Accidents and casualties have been for the most part of an unimportant character and in no instance fatal. "This is a matter for congratulation, because the number of suicidal cases have been very numerous, and at one time there were no less than four patients admitted with cut throats within a few weeks of one another." Temporary buildings to accommodate 50 males and 50 females in two blocks were commenced in October, 1898, and will be shortly occupied. In June there was an outbreak of scarlet fever on the male side, and 16 persons were attacked, but all the cases had a non-fatal termination. The origin of the outbreak could not be traced, but there was a considerable epidemic in the neighbourhood at the time. Lectures were given to nurses and attendants during the winter to qualify for the certificate of the Medico-Psychological Association, and no less than eight nurses and 13 attendants were successful in obtaining certificates. The Lunacy Commissioners in their report draw attention to the fact that post-mortem examinations were made in only 34 per cent. of the fatal cases, and they "regret that so few post-mortems should be made here in comparison with most other asylums," for much importance is attached by them to the practice. Influenza appeared during the year and attacked 19 patients and 12 members of the staff. The number of patients deemed to be actually suicidal is returned as 75, or 8 per cent. of the total number resident, and the Lunacy Commissioners point out that "a staff of the strength which exists here must find it impossible to obey strictly the injunction of the cautionary parchment issued for these patients that they should never be left alone. It may be a question whether the feeling by attendants that this is so may not lead to a perfunctory discharge of the duty." The sanatorium is badly furnished with exits in case of fire, there being but one central staircase, and the Commissioners urge "that the defect should be somehow remedied. The medical records are duly kept. We must

express the opinion that with the addition of 100 patients to be housed in the iron buildings the services of a third assistant medical officer will be necessary." A third assistant medical officer has since been appointed.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Extent of the Famine.—The Prospects of the Plague Epidemic.—A New Policy in Calcutta.

THE gifts of grain and money which are being sent from all parts of the world to relieve the starving natives of India show very imperfectly the real state of affairs. The accompanying table, which gives the number of persons in receipt of relief during the two weeks ending June 23rd in each province, pictures the enormous numbers affected as well as the widespread character of the distress:—

Name of Province.	Week ending June 16th.			Week ending June 23rd.			Increase or decrease.
	Relief works.	Gratuitous relief.	Total.	Relief works.	Gratuitous relief.	Total.

* Figures incomplete. † Return for the Umbala district wanting; the previous week's figures have been included.
‡ Returns for the States of Kherwara, Dungapur, Kotra, and Kushalgarh in Rajputana, and for the States of Dewas (Senior and Junior Branches), Bagli, Pathari, and Karaudia in Central India, are wanting; the previous week's figures for these States have been included.

The Bengal Government have just issued a letter concerning the prevalence of cases of plague in certain areas of Calcutta and directing that those areas should be more extensively disinfected. It is suggested by Government that disinfection of the entire tenement in which a case of plague has occurred should be carried out, the principle underlying the memorandum being that wider measures of disinfection should be practised. This seems at first sight a very reasonable policy; but it is by no means novel. The extraordinary part of this plague measure is that it is not accompanied by the conferring of any further powers on the plague authorities. The person who enters a tenement where a case of plague does not exist or has not existed is a trespasser and the authorities have no legal powers. The only way to carry out this extra disinfection is by an assumption of legal power which the officers do not possess. It would be much more straightforward to say outright that wholesale disinfection has got to be done, and that the officers concerned will have the full legal powers to perform it. At the present time it is not uncommon, I am informed, for offers of disinfection to be rejected. Considering that this measure of disinfection is now the sum and substance of all plague policy it seems extraordinary that it should be left to the will of the people. The consequence is that a very large number of houses which ought to be disinfected escape being treated.

June 28th.

I have to record a still further diminution in the number of deaths from plague throughout India. Last week there were only 282 deaths officially returned as due to plague. Of these, 106 occurred in Bombay and 108 in Calcutta. The North-West Provinces, the Punjab, the Central Provinces, Rajputana, and Aden were clear. Bombay city still returns a high general mortality—viz., 1048 for last week—a rate of over 66 per 1000 per annum. There were only 89 deaths from cholera returned and no other epidemic disease exists to explain the excess. It is pretty obvious that plague continues and is unrecognised to a much larger extent than is supposed. This rapid diminution in the mortality from plague in all parts of India must not be allowed to lull us into false hopes of a final disappearance of the disease from the country. The chances seem to be that while certain places hitherto severely attacked may not suffer so markedly in the future there are numerous areas only recently infected which will go through a series of recurrences.

THE SWANSEA GENERAL HOSPITAL.—The annual general meeting of this institution was recently held under the presidency of Colonel Morgan. The report stated that 892 in-patients had been admitted during 1899, the daily average number of occupied beds being 90·1, against 84 in 1898. The out-patients numbered 4392. The financial statement showed that during the year the adverse balance was reduced from £1391 to £845. The annual income was greater by £244. The workpeople's contributions showed an increase of £359, Baroness Patti-Cederstrom's concert realised £360 for the charity, and the house-to-house collections reached £418. During the year several much-needed improvements had been carried out in the building.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Enteric Fever in the City of Chichester,[1] by Dr. THEODORE THOMSON and Colonel J. T. MARSH, R.E.—This inquiry was ordered by the Local Government Board in response to local appeal from Chichester for help to ascertain the reason of the excessive typhoid fever prevalence in that city in recent years and particularly in 1898. The liability of this town to repeated recurrence of enteric fever in serious amount was well known and investigations had already been made by the Local Government Board in previous years.

The present area of Chichester is 1595 acres and its population is estimated at about 11,500. In general it may be said to stand on a gravel flat overlying clay of the London and Reading beds. Its water is derived partly from private wells sunk in the gravel but principally from a public supply obtained from deep wells in the chalk. Excrement disposal is effected either by water-closets or by cesspit privies; water-closets drain either to the sewers or to cesspools. An extensive and apparently well designed sewerage system was carried out in 1893-95, and nearly three-fourths of the houses now drain to the sewers. The principal difficulty with Chichester sewers has been to exclude subsoil water. Notwithstanding many alterations since the sewers were laid down subsoil water is still admitted in very large quantities; correspondingly, no doubt, sewage escapes into the subsoil water. Enteric fever prevalence in Chichester may be illustrated by the following table given by the inspectors:—

Period.	City of Chichester.			England and Wales: enteric fever death-rate per 1000 living.
	Estimated population.	Enteric fever deaths.	Enteric fever death-rate per 1000 living.	
1871-75	7,890	11	0·28	0·37
1876-80	8,020	26	0·65	0·28
1881-85	8,040	17	0·42	0 22
1886-90	7,920	12	0·23	0·18
1891-95	7,760	3	0·08	0·17
1896-98	11,000	21	0 64	0·17

It will be noticed that typhoid fever mortality in Chichester, having been in excess of that of England and Wales throughout the 15 years 1876-90, fell below it in 1891-95, but again rose to a very high level in the three years 1896-98. As regards notified cases of the disease, in 1896 there were 116, in 1897 there were 129, in 1898 there were 100, and in 1899, according to a postscript to the report, 76 cases had occurred up to the end of September. Dr. Thomson gives an account of a comprehensive study of the incidence of enteric fever on locality in Chichester, illustrated by two series of maps. One set shows the position of invaded dwellings in each of the years 1896, 1897, and 1898—the dates on the maps themselves have evidently been misprinted—another shows the distribution of deaths referred to enteric fever and continued fever during (*a*) the period 1870-84 and (*b*) the period 1885-98. This last set is instructive. No safe conclusions as to distribution of enteric fever on locality could be drawn from the comparatively small number of deaths in any given year, but in the combinations of 15 and 14 years, notwithstanding obvious possibilities of error, there is a much greater chance of obtaining an approximation to the facts. Similar maps might be constructed with advantage for other places than Chichester.

Study of the maps shows that in the three years 1896-98 enteric fever has shown a distinct preference for particular quarters of Chichester, especially certain parts which lie outside the line of the old city walls. During the remaining 25 years under consideration, however, the distribution does not always appear to have been the same. Thus in the earlier years the area within the line of the city walls seems to have had no such comparative immunity from typhoid fever as has latterly been the case.

Space does not allow us to follow Dr. Thomson in his discussion of the sundry causes of enteric fever in their possible application to the phenomena of its endemic prevalence in Chichester. After exhaustive consideration he is able to eliminate from any important share in the maintenance of the disease the consumption of infected milk and shellfish—no reference is made to other foods which occasionally have been known to convey typhoid infection—the use of infected drinking-water, infection by way of sewers, changes in rainfall, and variations in level of the subsoil water. Accusations which some of the inhabitants of Chichester appear to have brought against their recent works of sewerage that these works had directly or indirectly brought upon the town the recrudesence of its enteric fever the inspectors show good grounds for disbelieving. There was not, as a whole, a disproportionately heavy incidence of fever on the sewered population, there was no parallelism between the behaviour of the fever in the several subdivisions of the town and the sewerage conditions of those subdivisions, nor were there any facts indicating that infective sewer air could have explained the local incidence. By a process of exclusion of the above factors the question of soil is arrived at. The localities specially affected during 1896-98 are considered in their relation to soil and to opportunities of soil pollution. One point is particularly worthy of attention—that the poorer neighbourhoods where the fouling of the soil is likely to be greater than elsewhere have during the three years 1896-98 suffered most heavily. Nevertheless this does not seem to have held good during the earlier period 1870-84, when no special preference for the poorest neighbourhoods seems to have been shown. Again, although in some instances there seems to have been a greater proportionate incidence of fever upon neighbourhoods where cesspit privies preponderate over cesspools, when the whole period is reviewed cesspool and cesspit privy neighbourhoods seem to have suffered in much the same degree. From these and many other considerations the inspectors conclude that the mere fact of there being abundant opportunities of soil pollution in Chichester does not suffice as an explanation of the long-continued prevalence of enteric fever in serious amount there. Nevertheless as a result of a careful investigation of local circumstances they are disposed to see a possible explanation in the existence of certain soil conditions peculiar to Chichester or which Chichester may share with other towns in which enteric fever is endemic. "Hypothesis of the existence in Chichester of soil conditions especially favourable to the viability and growth of the infective material of enteric fever is not inconsistent with the facts ascertained by us and set out in this report. But, on the other hand, such hypothesis, while not inconsistent with these facts, does not at present afford an adequate explanation of features that have characterised the fever in its distribution in time and place in Chichester. Fuller knowledge of soil conditions in their relations with fever prevalence may account for these features; without that knowledge it is not possible to arrive at definite conclusions." Few will question the desirability of further research into the subject. Not the least valuable part of this report is that containing suggestions as to the lines upon which an inquiry should be conducted, which is "urgently called for in the interests not only of Chichester but also of not a few other localities in this country where enteric fever is endemically prevalent in such amount as to take year after year a toll of deaths greatly in excess of the proportion claimed by this disease in England and Wales as a whole."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6470 births and 3476 deaths were registered during the week ending July 14th. The annual rate of mortality in these towns, which had been 15·1 and 14·5 per 1000 in the two preceding weeks, rose again to 15·6 last week. In London the rate was 14·2 per 1000, while it averaged 16·5 in the 32 provincial towns. The lowest death-rates in these towns were 9·6 in Portsmouth, 11·1 in West Ham, 11·3 in Brighton, and 11·5 in Croydon; the highest rates were 19·7 in Oldham, 19·8 in Newcastle, 20·0 in Manchester and in Gateshead, and 20·9 in Liverpool. The 3476 deaths in

these towns included 427 which were referred to the principal zymotic diseases, against 419 and 344 in the two preceding weeks; of these 104 resulted from measles, 102 from diarrhœa, 96 from whooping-cough, 72 from diphtheria, 27 from "fever" (principally enteric), 24 from scarlet fever, and two from small-pox. No fatal case of any of these diseases occurred last week in Norwich; in the other towns they caused the lowest death-rates in Portsmouth, Bolton, Preston, Bradford, and Leeds, and the highest rates in Cardiff, Derby, Sheffield, and Gateshead. The greatest mortality from measles occurred in Derby, Oldham, Sunderland, and Newcastle; from whooping-cough in Derby, Burnley, Sheffield, and Gateshead; from "fever" in Huddersfield and Wolverhampton; and from diarrhœa in Blackburn, Sheffield, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 72 deaths from diphtheria included 26 in London, nine in Leicester, five in Cardiff, five in Salford, and five in Sheffield. One fatal case of small-pox was registered last week in Liverpool and one in Oldham, but not one in any other of the 33 large towns. There were 17 cases of small-pox in the Metropolitan Asylums Hospitals on Saturday last, July 14th, against 16 and 17 at the end of the two preceding weeks; four new cases were admitted during the week, against eight and four in the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1861, against numbers increasing from 1754 to 1843 in the five preceding Saturdays; 208 new cases were admitted during the week, against 219, 210, and 229 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 268 to 140 in the five preceding weeks, rose again to 160 last week, but were 26 below the corrected average. The causes of 34, or 1·0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Hull, and Newcastle; the largest proportions of uncertified deaths were registered in Brighton, Birmingham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·9 and 17·7 per 1000 in the two preceding weeks, further declined to 17·2 per 1000 during the week ending July 14th, but was 1·6 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 10·6 in Leith and 15·1 in Aberdeen to 18·1 in Edinburgh and 20·5 in Dundee. The 533 deaths in these towns included 23 which were referred to diarrhœa, 21 to whooping-cough, 17 to measles, seven to scarlet fever, four to diphtheria, one to small-pox, and not one to "fever." In all 73 deaths resulted from these principal zymotic diseases, against 83 and 85 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had increased from 19 to 32 in the three preceding weeks, declined again last week to 23, of which nine occurred in Glasgow, five in Greenock, two in Edinburgh, two in Dundee, two in Aberdeen, and two in Paisley. The deaths from whooping-cough, which had been 26 and 22 in the two preceding weeks, further declined to 21 last week, and included 12 in Glasgow, two in Dundee, and two in Paisley. The fatal cases of measles, which had risen from 14 to 20 in the three preceding weeks, declined again last week to 17, of which nine were registered in Glasgow, six in Edinburgh, and two in Paisley. The deaths from scarlet fever, which had been seven and four in the two preceding weeks, rose again to seven last week and included five in Glasgow. The fatal cases of diphtheria, which had been two in each of the two preceding weeks, rose last week to four, of which three occurred in Glasgow, where the fatal case of small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 97 and 72 in the two preceding weeks, further declined last week to 71, but exceeded by 18 the number recorded in the corresponding period of last year. The causes of 35, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·0 and 17·8 per 1000 in the two preceding weeks, rose again to 18·2 during the week ending July 14th. During the past four weeks the death-rate in the city has averaged 18·5 per 1000, the rate during the same period being 13·9 in London and 17·1 in Edinburgh. The 122 deaths belonging to Dublin registered during the week under notice were three in excess of the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against three and six in the two preceding weeks; of these, four resulted from whooping-cough, three from "fever," and one from diarrhœa. These eight deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·9 in Edinburgh. The fatal cases of whooping-cough, which had been one, two, and three in the three preceding weeks, further rose to four last week. The deaths referred to "fever," which had been two, nil, and one in the three preceding weeks, rose last week to three. The 122 deaths in Dublin last week included 16 of infants under one year of age and 28 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons exceeded the number recorded in the preceding week. Eight inquest cases and five deaths from violence were registered; and 60, or nearly one-half, of the deaths occurred in public institutions. The causes of two, or 1·7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Deputy-Inspector-General H. T. Cox is appointed to Plymouth Hospital.

ROYAL ARMY MEDICAL CORPS.

During the absence on leave of the Principal Medical Officer in Ireland till August 4th his duties will be performed by Lieutenant-Colonel F. G. Adye-Curran. Surgeon (on probation) A. D. Jameson has arrived in London for temporary duty. Major F. M. Baker, from half-pay, to be Major, with precedence next below Major S. C. B. Robinson, vice J. Minniece, deceased. Lieutenant-Colonel Samuel James Flood retires on retired pay on account of ill-health. Temporary Lieutenant George Black. Surgeon-Lieutenant 2nd Volunteer Battalion the Royal Sussex Regiment, is granted the temporary rank of Captain whilst employed in South Africa.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the promotion of Lieutenant-Colonel John Thomas Brownrigg Bookey, Bengal Establishment, to Colonel. Her Majesty has also approved of the retirement from the service of the undermentioned officers:—*Bengal Establishment:* Lieutenant-Colonel Charles Joseph McCartie, Lieutenant-Colonel Dennis Wood Deane Comins, and Lieutenant-Colonel John Francis Tuohy.

VOLUNTEER CORPS.

Submarine Miners: The Severn Division: John David Williams to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the King's Own (Royal Lancaster Regiment): Captain Richard John Morris resigns his commission and is appointed Surgeon-Lieutenant. 2nd Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Lieutenant W. Roxburgh to be Surgeon-Captain. 1st Volunteer Battalion the Northamptonshire Regiment: Surgeon-Captain E. P. Dickin resigns his commission. 1st Volunteer Battalion the Gordon Highlanders: John Farquhar Christie to be Surgeon-Lieutenant. 24th Middlesex: Surgeon-Captain J. D. Grant to be Surgeon-Major.

TRANSVAAL WAR NOTES.

Lieutenant-Colonel Kenny, R.A.M.C., Major Tuke, R.A.M.C., Major Blenkinsop, R.A.M.C., and Major Hathaway, R.A.M.C., left Cape Town invalided in the *Aurania* on July 7th for England.

We understand that the Sick and Wounded Officers' Surgical and Medical Aid Committee, originally formed to provide medical and surgical aid for those who have suffered in South Africa, are equally prepared to render assistance to

officers returning home from other theatres of war. Applications should be addressed to the Hon. Arthur Brodrick at Hampden House.

The *Times* announces that in connexion with Princess Christian's Homes of Rest for Discharged Soldiers and Sailors now in course of erection at Bisley, Her Majesty the Queen has been graciously pleased to endow two beds, their Royal Highnesses the Duke and Duchess of York endow one bed for a soldier or sailor, her Royal Highness Princess Christian of Schleswig-Holstein one bed for the King's Royal Rifles, and their Highnesses Princess Victoria of Schleswig-Holstein and Princess Aribert of Anhalt a bed for a "Greenjacket."

The following steamships have arrived at Southampton carrying invalids and wounded men from South Africa. The *Kildonan Castle* arrived on July 11th and the *Dunera* on July 12th. From the former 100 patients were admitted at the Royal Victoria Hospital, Netley, and from the latter 11 cases. Only the severe cases were sent to Netley, the remainder being sent on to other stations. At Netley eight wards are now full of patients suffering from enteric fever.

Major A. S. Rose is in medical charge of the hospital ship *Avoca* which left Southampton for South Africa on July 18th.

Lieutenant Morris, R.A.M.C., has left England for duty in South Africa.

THE SOUTH AFRICAN COMMISSION.

This matter has now been definitely settled and the commission has been increased from three to five by the addition of two lay members with undeniable business qualifications. An objection was raised from the first to one of the three eminent names submitted by the Government. It is absurd to suppose that a man of the high personal character and integrity of Professor Cunningham will not bring to the work a perfectly unbiased judgment; it would be an insult to him to suppose otherwise. It is rather on the score of his scientific attainments in a special direction that we ventured to think that a man of far less scientific reputation might have proved better adapted and more useful for conducting such an investigation. We think, too, that the commission will, in the first instance, have to learn its business from the evidence that will be brought before it, and that for various practical reasons it would have been well if it had someone at hand well versed in military systems. There was no reason why such an individual should have taken part in the deliberations of the commission or signed its report. But it has been ruled otherwise. We may call our readers' attention to an article in the *Standard* of July 18th on the subject of this commission.

DEATHS IN THE SERVICES.

Surgeon-Lieutenant-Colonel William Wellington Lake, M.M.S.C., Volunteer Company Royal Army Medical Corps, at Bloemfontein of Bright's disease, on July 13th. Educated at St. Thomas's Hospital, he was admitted a Licentiate of the Royal College of Apothecaries in 1876, and a Member of the Royal College of Surgeons of England in 1877. In 1898 he was appointed surgeon-major of the Militia Medical Staff Corps and volunteered for service and went to South Africa with the Volunteer Company of the Royal Army Medical Corps in the early part of this year. For active service in the field as a surgeon in the Ottoman army he received the medal and the fourth class of the Medjidieh for his services during the Russo-Turkish war of 1877-8. Mr. Wellington Lake held many public appointments, among them being those of deputy coroner for West Surrey and medical officer of health for the Guildford and Woking districts of the same county.

THE ASHANTI CAMPAIGN.

With so many other and bigger matters on hand in China and South Africa it is not surprising that recent events in Ashanti and the little campaign for the relief of Kumasi have been comparatively lost sight of. But there has been a fine exhibition of British courage, endurance, and skilful management of late in this very unhealthy and malarious part of the world. What with the fighting with savages and fever, short rations, flooded districts, and trying marches there must have been a good number of wounded and a great deal of sickness, and the wonder is whether medical aid, quinine, and suitable or even sufficient food for the sick were obtainable. It seems to be nearly certain, however, that Colonel Willcocks has succeeded in relieving the hard-pressed garrison at Kumasi.

LEAN'S ROYAL NAVY LIST.

Lean's Royal Navy List, published by Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill, price 7*s.* 6*d.*, is so well known and is of such practical utility that scarcely anything is required but a reminder to our readers that a new issue is ready. We note, however, that the July issue of this quarterly "complete encyclopædia of our first line of defence," which is now ready, includes the war and meritorious services in South Africa of naval officers connected with that campaign.

THE ORDER OF THE MEDJIDIEH.

The Queen has given her Royal authority that Major Richard Hugh Penton, D.S.O., R.A.M.C., may accept and wear the insignia of the Imperial Ottoman Order of the Medjidieh (third class) conferred by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey in recognition of service in the Soudan during the year 1899.

MILITARY HOSPITAL, DEVONPORT.

280 invalid soldiers arrived at the Military Hospital, Devonport, on July 14th, and 350 were disembarked at Plymouth subsequently.

Correspondence.

"Audi alteram partem."

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editors of THE LANCET.

SIRS,—We again beg for the powerful aid of the press on behalf of the Factory Girls' Country Holiday Fund. Owing to the liberal help of the public we were able last year to give a country holiday of a week or more to 2200 working girls and women employed in all parts of London in factories and workshops. So many are again waiting to go that we are compelled to make a very urgent appeal for funds. Many of these toilers know nothing of the delights of country life and surroundings. Those who have been away appreciate the change and rest more every year and for months save a few pence weekly out of their scanty earnings towards their expenses; £515 were contributed by them in this way last year. They are sent to the seaside and to country villages, and the greatest care is taken in making all arrangements for their holiday. The cottagers with whom they are boarded and the ladies, clergy, and others who look after them during their stay do their utmost to give them a happy holiday; the cottagers in many cases beg to have the same visitors year after year. When it is remembered that many of the girls are little more than children of 14 years of age and upwards, spending the best part of their lives in hot crowded factories, and that in many cases they are in large measure the bread-winners of the family, we feel sure that their claim for a short holiday in fresh air and country surroundings with freedom from daily toil and worry will not be disregarded.

We are, Sirs, yours obediently,

(Signed) M. LONDIN,

THE NEED FOR REFORM IN DEATH REGISTRATION.

To the Editors of THE LANCET.

SIRS,—A few weeks ago the vestry of Plumstead addressed a letter to the Westminster vestry informing them that in the Plumstead registration district almost 3·5 per cent. of the deaths were uncertified either by a medical practitioner or by a coroner. As this seemed a large percentage of uncertified deaths in one district alone I took some trouble in finding out how the law stands at present and how its provisions are carried out. At the outset I was appalled to discover that it is apparently

not necessary for the cause of death to be certified by a medical practitioner or by a coroner. In fact, it seems fairly clear that all the law demands is *registration* and not *certification*, and that the act of registration without certification is made easy in some districts and difficult in others. The act of registration is performed by the registrar, who need not necessarily have information either from a medical practitioner or a coroner, but can register a death on the information of a layman present at the death—"a qualified informant"—if he has no reason to suppose that the death was due to violence or accident or occurred under suspicious circumstances. These last must be referred to the coroner.

A Committee of the House of Commons was in 1893 appointed to consider the question and amongst other recommendations the following is particularly noticeable: "Your Committee ..... have come to the conclusion that uncertified deaths should as a class cease to exist and that means should be devised whereby a medical certificate should be obtained in every case not certified by a registered medical practitioner in attendance." The reason given for this is that there is no uniformity of practice amongst registrars and that in some districts cases are registered which in others would be referred to the coroner. Most uncertified deaths occur amongst infants and especially amongst illegitimate children, and it is not difficult to see how, in the case of infants, registration without certification makes murder easy. From the report of the Committee it is evident that uncertified deaths are on the whole diminishing steadily, but further examination of the figures shows that in some districts the percentage is still very large, and that it is extremely probable that under the existing law there will always be an irreducible minimum. To get rid of this quantity an alteration of the law is urgently necessary. The Committee recommended that a medical certifier should be appointed to make a personal inquiry into all uncertified deaths. They further recommended that he should be the medical officer of health, and probably their recommendation is the best one, though there are several reasons against it. The only other medical man likely to be appointed would be the police surgeon, but there would be in the public idea great sentimental opposition to a police surgeon inquiring into a cause of death. It would immediately create objection as implying suspicion of foul play. But whoever the certifier may be I am sure that he should not be allowed to perform a post-mortem examination without a coroner's order and that he should always send his report to the coroner, and that the latter should be, as now, the authority for determining whether an inquest should be held or not. That an alteration of the law is necessary has been asserted by a Committee of the House of Commons, whose recommendation has been approved by the London County Council, by the Society of Medical Officers of Health, and by the Coroners' Society.

I am, Sirs, yours faithfully,

Buckingham Gate, S.W., July 16th, 1900. H. A. DES VŒUX.

"THE COMPARATIVE GERMICIDAL ACTION OF SOME DISINFECTANTS."

To the Editors of THE LANCET.

SIRS,—I have read Mr. A. H. Burgess's article under the above heading in THE LANCET of June 23rd (p. 1797) with much interest and no little surprise. The results set forth in the article are of such an extraordinary nature and so altogether opposed to those obtained by myself when working with many of the same disinfectants that I feel constrained to express considerable doubt in the efficiency of the *thread method* as employed by Mr. Burgess. This method was condemned as long ago as 1890 by Dr. V. von Gerlach. Commenting on the results obtained by Rémouchamps and Sugg when estimating the comparative value of certain preparations of phenol and cresols—in *solution* and *emulsion*—Von Gerlach states that he suspended threads in solutions and emulsions of phenoloids for an hour, after which he hung them for another hour in about 400 cubic centimetres of water, at the expiration of which time the threads which had been suspended in the emulsions "smelt plainly of the disinfectant," and that he "had to ascribe absence of growth in the gelatin to insufficient washing of the threads, *as subsequent inoculation with vigorous cultures proved*." From which it will be seen that when working with emulsions there must ever be a certain amount of doubt attaching to investigations carried out with this method, as an alternative to which I should like to recommend one I have employed in several thousands of experiments with most regular and consistent results. This method has the further advantage of being extremely simple. Briefly stated it is as follows. To a known volume of an active culture of the organism add an equal volume of the dilute disinfectant; shake and take sub-cultures in suitable media at definite intervals. Incubate for at least two days at 37° C. In practice I prefer to take five cubic centimetres of a 24-hours' blood-heat culture of the organism to five cubic centimetres of, say, 0·2 per cent. disinfectant. This reduces the percentage of the latter to 0·1. (I may add the disinfectants are allowed to act at a room temperature of about 15° C.) Sub-cultures are then taken every two and a half minutes up to 15 in tubes containing about 10 cubic centimetres of bouillon. No exception can be taken to this method as regards the introduction of disinfectant during inoculation. I have made careful weighings and find that any disinfectant in the bouillon tubes introduced with the "loopful" employed in inoculation is present in such an extreme state of dilution (1 in 6,000,000) as to be quite innocuous.

I am, Sirs, yours faithfully,

Clapham, S.W., July 14th. J. T. A. WALKER.

PADDLING IN THE SEA.

To the Editors of THE LANCET.

SIRS,—My object in writing is to try to do a good turn to the thousands of children who are now going to the seaside. For some reason or other paddling is very generally condemned by the medical profession. My own experience, extending over some 30 years, is that the practice is most beneficial. The children love it and a child who has once paddled, when at the seaside always craves to do it again. I have no idea on what grounds the medical objection is based, but for some reason or other the prohibition is strongly impressed on the parents. The parents think the cold water to the feet sends the blood to the head, and believe that the hot sun on the head and the cold water to the feet are injurious. No doubt the same blood which is cooled in the legs is circulating through the brain and certainly the children's legs are red after paddling, so I suppose if it does anything it what people call "draws blood" to the legs and tends to prevent congestion elsewhere. A child on a very hot day is fretting and sweating, but a child paddling on such a day is perfectly happy and does not feel the heat. There is certainly no undue fatigue in standing, walking, or trotting about in the shallow water. Paddling seems a trivial subject for a letter in THE LANCET, but I am so convinced that it does the children good that I trust this may get inserted.

I am, Sirs, yours faithfully,

WM. KNIGHT TREVES, F.R.C.S. Eng.

Margate, July 12th, 1900.

THE JOINT COMMITTEE TO OPPOSE MIDWIVES REGISTRATION: AN APPEAL FOR FUNDS.

To the Editors of THE LANCET.

SIRS,—I have been directed to request the favour of space and permission to appeal to the readers of THE LANCET for donations to the voluntary fund to carry on the work of this committee. Its operations thus far have, on very limited resources, been most successful, being based on the broad principle of maintaining the rights of the profession as essential to the public welfare. Memorials to Members of Parliament have been well signed in large and important centres, and signatories have besides given letters introducing the representative of my committee, who has thus obtained personal interviews with about 20 and correspondence with over 30 Members of Parliament on the influential introduction of electors. Of these the most successful were the memorials and introductions of Mr. Griffith-Boscawen's medical constituents, securing his valued support, serviceable motion to consider the Bill "upon this day three months," and admirable speech imparting a new and improved tone to the debate.

Although the Bill is probably dead for this session very vigorous action is necessary in the constituencies to rouse

medical electors to bring home to Members of Parliament the real nature and grave danger of the proposed recognition of midwives by law to render *medical services* in labour. The registration of midwifery or monthly nurses is not opposed. The distinction taken is that diagnosis of presentation and conditions in labour is a difficult and highly responsible medical service which can be safely entrusted only to medical skill and knowledge. This my committee finds Members of Parliament readily grasp A medical Parliamentary division has been formed at Lewisham for local medico-political work. For the extension and organisation of our work in Parliamentary divisions funds are urgently required. About £30 have been expended, but to carry out our procedure throughout England and Wales at least £200 are needed.

Donations may be sent to the honorary treasurer, Dr. F. Lorimer Hart, Kirkdale, Sydenham, S.E., and further information may be obtained from the honorary secretaries, Mr. R. B. Anderson, and Mr. S. R. Russell Matthews, at the secretarial address, 32, Montague-place, London, W.C.

I am, Sirs, yours faithfully,

July 18th, 1900. F. S. TOOGOOD, M.D. Lond., Chairman.

"THE NATIONALISATION OF TRINITY COLLEGE, DUBLIN."

To the Editors of THE LANCET.

SIRS,—The controversy in THE LANCET on the above subject will, I feel sure, have convinced your readers not only that Irish university education is a difficult and thorny question, but that it is futile to put forward "the nationalisation of Trinity College, Dublin," as a settlement of it until there is some agreement as to what this phrase really means.

Your correspondent "A.M., M.D. Dub. University," says that what he understands as "The Nationalisation of Trinity College, Dublin," is its "desectarianising" *plus* the removal and endowment of its divinity school. On the other hand, I hold that the "complete desectarianising" of Trinity College will not make it a "national" university or college. To "nationalise" a university or college you must have among its governing body—professors, Fellows, and officials—representatives of all classes and creeds. Irish Roman Catholics and Presbyterians must have a fair share in its government and administration; the other existing colleges in Ireland must have their claims duly recognised; and, finally, the degrees of a "nationalised" university must be thrown open freely to the members of both sexes.

Now, Sirs, suppose—to look at the question from a practical point of view—a statesman of either of the great political parties adopts as the solution of the Irish University question, "the nationalisation of Trinity College, Dublin," in the narrow sense recommended by your correspondent, and brings forward such a measure in Parliament. He will soon find that he will be opposed, as indeed "A.M., M.D. Dub. University" freely admits, by the authorities of Dublin University; the Presbyterians of Ireland (who number 446,687) would not accept such a solution of the question because they would have no adequate representation on the governing body; the other colleges in Ireland would be up in arms against such a scheme, fearing their extinction; the Irish Roman Catholics would also decline to accept such a settlement; and women of all political parties would protest against the establishment of any new, or the rearrangement of any old, university unless all its degrees were open to their sex. No statesman, not even "a Government endowed with a backbone" (to quote your correspondent) could overcome such opposition. If, on the other hand, the statesman would propose as his measure the more thorough nationalisation of Trinity College, Dublin, such a scheme as I have foreshadowed, it would be opposed even more fiercely by the authorities of Trinity College, and I am sure it would not satisfy the demands of the Roman Catholic hierarchy in Ireland, and so the statesman after such unfortunate experiences would be compelled to agree with your original view—"the proposal to nationalise Trinity College is therefore as useless as it is impracticable"—while, I may be allowed to add in conclusion, adopting the classical diction of "A.M., M.D., Dub. University," no one "outside the walls of a lunatic asylum" would put forward as the settlement of Irish University education any form of "nationalisation of Trinity College, Dublin."

I am, Sirs, yours faithfully,

July 17th. IRISH GRADUATE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine: Official Recognition by the Government.

THE Liverpool School of Tropical Medicine, which had only received partial recognition, has now been fully recognised by the Government as a training school for medical men proceeding to the colonies to take up Government appointments. Mr. Chamberlain, in a complimentary letter recently addressed to Mr. Alfred L. Jones, the chairman of the school, expressed his appreciation of the admirable work which is being done by the school, together with his cordial good wishes for the success of the new expedition in connexion with the school which had recently sailed for the region of the Amazon. Mr. Chamberlain concluded a flattering letter by intimating that the steps necessary to give effect to his decision will be taken at an early date. Lord Salisbury has also informed Mr. Alfred Jones that all medical officers proceeding to the African protectorates under the administration of the Foreign Office will be required to undergo a course of instruction for two months, either at the London or the Liverpool school of tropical medicine. The enterprise and public spirit shown by the Liverpool School of Tropical Medicine in the despatch within 12 months of three expeditions to the tropics for the elucidation of the causes of malaria, dysentery, and yellow fever, fully entitled it to official recognition by Government (in conjunction with the London School of Tropical Medicine) as a training school for colonial medical officers. Liverpool is to be congratulated on the position which its school of tropical medicine will now take in the world, and there can be no doubt that, with such an auspicious beginning, it will go on and prosper.

Liverpool Stanley Hospital.

The vacancy on the staff of physicians at the Stanley Hospital, through the resignation of Dr. C. J. Macalister, has been filled by the appointment of Dr. R. J. Buchanan, assistant physician. Dr. Buchanan had a successful career at the medical school of University College, Liverpool, and his promotion to the higher post at the Stanley Hospital is fully endorsed by his professional brethren. The method of election in the matter of proxies was taken exception to by the other candidates, and there can be no doubt that the system ought to be abolished. The electorate at this hospital is cumbersome, consisting of some hundreds of subscribers of one guinea and upwards, so that here also there is room for an improved method of election to the higher medical posts.

The Joint Parochial Hospital for Tuberculosis.

The joint committee of the unions of Liverpool, West Derby, and Toxteth Park have decided to purchase land at Heswall for the erection of the joint parochial hospital for tuberculosis at a cost of about £4200. The site of the new hospital is a pleasant plot of land on the slope of the hill overlooking the river Dee and the distant Welsh mountains. Mr. C. H. Lancaster has been appointed the architect and he is now engaged on the plans of the proposed building.

Low Death-rate in Liverpool.

The medical officer of health reports the interesting fact that there were 64 deaths less during the week ending July 7th than in the corresponding week of last year, the rate of mortality being 18·2 per 1000 of the inhabitants as compared with 23·2 per 1000 at the same period of last year, when there were 299 deaths.

Liverpool Country Hospital for the Chronic Diseases of Children.

The garden fête which was held last week at Woolton Wood, the residence of Mr. Holbrook Gaskell, in aid of the funds for the proposed Country Hospital for the Chronic Diseases of Children realised £528 2*s.* 6*d.* The institution, which commenced work in November, 1899, has a temporary home in the Children's Convalescent Institution at West Kirby, in which 20 beds were placed at the disposal of the committee at an annual rental. Mr. Holbrook Gaskell announced his intention of giving a second donation of £1000, whilst Mr. Andrew Gibson promised £500 towards the purchase of the new site. These donations are in addition to those already announced in THE LANCET.

The Heath Essay of the University of Durham.

The Heath Scholarship of the value of £200 has been

awarded to Dr. Nathan Raw, medical superintendent of the Mill-road Infirmary, Liverpool, and Major J. R. Dodd, R.A.M.C. The Heath Essay, which was founded by the late Professor Heath, is awarded every two years to graduates of the University of Durham. The subject of the essay for this year was "The Urinary Tract, its Injuries and Surgical Diseases, their Pathology, Diagnosis, and Treatment." Dr. Raw has also recently been elected a Fellow of the Royal Society of Edinburgh for his valuable contributions on the subject of tuberculosis with which his name has become identified in Liverpool. It is an interesting fact that the Heath Scholarship was awarded four years ago to Mr. G. P. Newbolt of Liverpool.

Death of Mr. Nicholas Smith Glazebrook.

Mr. N. S. Glazebrook, M.R.C.S., L.S.A., died at his residence, Hayman's-green, West Derby, on July 14th, in his eighty-eighth year. The deceased was at one time one of the best-known practitioners in the suburbs of Liverpool. He was closely associated with the public life of Liverpool in many of its phases, and for many years was a member of the West Derby Local Board. The deceased's eldest son is the Director of the National Physical Laboratories and was for some time the principal of University College, Liverpool—Mr. Richard Tetley Glazebrook, M.A., F.R.S. The interment took place on July 17th, at the parish church, Knotty Ash, amidst universal demonstrations of public respect.

July 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

AT a meeting of the Edinburgh University Court held on July 16th it was intimated that the Court's Ordinance No. 1 (Separation of the Teaching of Medical Jurisprudence or Forensic Medicine and Public Health in the University of Edinburgh) had been approved by Her Majesty in Council and that therefore the ordinance would come into force as from Oct. 1st next. Various grants were made from the Earl of Moray's endowment for purposes of original research, the recipients being Professor E. A. Schäfer, Dr. Alfred C. Sandstein, Dr. H. E. Gibbs, Dr. John S. Flett, Dr. J. Wilson Dougal, Dr. Evan H. Fraser, and Dr. Sutherland Simpson. Recognition was again granted to the Edinburgh Medical College for Women for the ensuing year.

Farewell Banquet to Sir William T. Gairdner.

On the occasion of Sir William T. Gairdner leaving Glasgow to reside in Edinburgh a considerable number of his medical and other friends entertained him to a banquet in the Windsor Hotel. In replying to the toast of the "Guest of the evening" in a pleasing and excellent speech Sir William Gairdner remarked that he had lived for 38 years before he was professor and 38 years after he had been appointed to a chair in Glasgow University, and that the two things he had ever asked for in life were his wife and his professorship. All the rest had come to him in spite of himself.

Health of Aberdeen.

Last week there were 38 cases of whooping-cough and 33 of measles reported to the medical officer of health, there being an increase in the number of cases of measles.

Thomson Medical Bursaries, Aberdeen University.

In consequence of the fall in the rate of interest the Senatus has been compelled to resolve that in future there shall under this foundation be three bursaries of £22 each, three of £20 each, and three of £18 each instead of six of £24 10*s.* each and three of £20 each, as hitherto.

July 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Belfast Workhouse.

THE Belfast Board of Guardians have in committee drawn up a report in reply to the scathing letter of the Local Government Board, which is a piece of ingenious special pleading. They admit that there has been a technical breach of the regulations, but they say that the irregular expenditure was upon necessary works; they are convinced that the best value was obtained for every penny, and that a large proportion of the outlay was incurred in connexion with the infirmary in carrying out repairs recommended by the Local Government Board, and of such a nature that they had to be carried out piecemeal and were unsuitable for contract. To break rules and then offer as an excuse that such irregularities are "technical" will not satisfy the Local Government Board. The guardians, had they been alive to their duties, ought surely to have been aware of such irregularities and in future the Belfast public will hold them responsible if they do not exercise a proper supervision over the official management of the institution. A discussion which took place on June 26th in reference to the salary of the new master does not tend to secure the confidence of the public. It was recommended in a report that this should be £250 per annum, and an amendment to make the sum £200 was only lost by the casting vote of the chairman. The proposed salary is much too low. Where can a man thoroughly versed in local government acts and in Poor-law procedure and who will manage the largest workhouse in the three kingdoms with over 3000 inmates be procured at this sum? A master of such an institution—a small town, in fact—whom every official and inmate would respect cannot be secured at such a paltry salary. This "penny-wise-and-pound-foolish" policy will only tend to incompetency and further mismanagement.

The Royal Victoria Hospital, Belfast.

From a report of the Working-men's Committee read at their annual visit to the Throne Convalescent Hospital on June 30th it appears that for the 16 months ending Dec. 31st, 1899, the sum of £3429 8*s.* 8*d.* was subscribed by the working-classes, this being the largest amount received from this source since the Working-men's Committee was formed 13 years ago. During the past 16 months 34,320 extern and 3255 intern patients have been treated at the Royal Victoria Hospital. The report concluded with the special thanks of the working-classes of the city to the medical and surgical staff of the hospital (as well as to the nurses) for the very efficient and gratuitous services rendered to the patients under their care.

Bangor District Nursing Society.

The annual meeting of this society was held under the chairmanship of the Marquis of Dufferin and Ava on June 26th. The report stated that the district nurse had attended 450 cases and had paid over 11,000 visits. There was a balance in the hands of the treasurer of £10 4*s.* 1*d.* An interesting speech was delivered by Lord Dufferin, to whom, as well as Lady Dufferin, the success of the society is largely due.

The Epidemic of Typhoid Fever in Belfast.

At a meeting of the Belfast City Council on July 2nd an animated discussion took place in reference to the outbreak of typhoid fever. Dr. H. Whitaker, medical officer of health of the city, reported that between May 20th and June 16th, 1900, 227 cases of typhoid had been notified and there had been 37 deaths. In the corresponding period of last year 152 cases of typhoid were reported with only 18 deaths. The discussion resolved itself far too much into a question as to whether it was the water or the sewage which was at fault in the outbreak, and as to the relative responsibilities of the city council and of the water commissioners. Very strong statements were made by some of the members of the city council as to the insanitary state of the streets, while equally incriminating remarks were made as to the water. By this line of discussion, however, no progress is made, and the Lord Mayor, who is a very practical man of business, said that if the water was bad the city council could bring the matter under the notice of the Local Government Board which could order an inquiry, and, he added, the Stoneyford water "had been subjected to the examination of the best analysts, and while they had not declared that it was a first-class water they found that it was a safe, healthy, and sound water." Finally, at the suggestion of the Lord Mayor, it was arranged that the Improvement and Public Health Committee should be instructed to consider the question of the health of the city, with the view of seeing what better provision could be made to improve it, and to report at an early date. The city surveyor has prepared an elaborate scheme for the bacterial treatment of the main drainage sewage which is at present emptied into the

Belfast Lough and which causes so much annoyance to the inhabitants living on each side of that estuary. To carry this plan out the Local Government Board will have to approve the works and to sanction the borrowing of £80,000 for their execution. It was decided, after a long discussion, to refer the matter to the council in committee and to employ a specialist to report on it.

A joint committee, formed of members of the Public Health Committee and Improvement Committee of Belfast who were appointed to consider the question of the health of the city and how it could be improved, with special reference to typhoid fever, has instructed the executive sanitary officer and the city surveyor to prepare reports on this important matter. The former recommends (1) that the sewers and drains be more efficiently cleansed, ventilated, and flushed; (2) that old courts, alleys, and back passages, and drains connected therewith, be flushed out; (3) that sewer atmosphere generated in the main drains be prevented from rising to the main levels of the city; (4) that the milk-supply of the city be more effectively controlled; (5) that the sale of shell-fish from Belfast Lough be prohibited within the city; (6) that a sufficient number of officers be provided for drain-testing (it is impossible for two officers, as at present, to do this duty for 71,000 houses); (7) that the domestic scavenging of Belfast be improved; and (8) that pollution of streams in the city be prevented, as was recommended in a report on Nov. 9th. These precautions, it is thought, will keep down the normal rate of typhoid fever (the endemic disease), but the executive sanitary officer reports that there will be no protection against epidemics of the disease until the Water Commissioners carry out the powers which they obtained from Parliament last year, when, in referring to their catchment, the chief engineer of that trust stated that "a condition of things like that on the catchment is a standing menace to the health and life of the people in the town where the water is consumed." The city surveyor agrees with these recommendations of the executive sanitary officer and adds suggestions as to structural improvements in the present sewage system of the city of Belfast. He advises more ventilation in many of the sewers and that arrangements be made that some of the higher parts of the city should not have more than their due share of discharge of sewer-gas as at present. He advises improved modern sewers for the old, leaky, and defective ones, more facilities for flushing sewers and house-drains, the use of the water-pressure test for the drains of all houses built on "filled-in" ground, and that "concreting" and "asphalting" should be required on all doubtful or "filled-in" sites.

The Illuminating Gas-supply of Dublin.

The alarm caused many months ago by the letter from Professor J. Emerson Reynolds warning gas consumers of the fact that the amount of the poisonous ingredient carbonic oxide had been much increased in the town gas has not been allayed by any definite statement from the Alliance Company. At the last meeting of the Dublin Sanitary Association an important discussion took place on the subject, and it was alleged that the ordinary coal-gas in use in Dublin up to February last, containing about 6 per cent. of carbon monoxide (such as seems to be unavoidable), was now replaced by a mixture of coal and water-gas containing as much as 17·9 per cent., indicating a mixture of about 40 per cent. of water-gas. The Alliance and Dublin Gas Consumers Company has long held a complete monopoly of our gas-lighting as an independent company outside the control of the municipal authorities or corporation. Their delay in affording any definite information available to the public as to the quality of the illuminant which they supply has naturally given much dissatisfaction, for it is alleged that many of their iron conduits for gas are old and so corroded as to allow of considerable leakage. The electric light cannot be widely used owing to the comparative failure of the corporation installation, and but very few private houses in Dublin are now supplied with it. There seems, moreover, but a poor prospect of their obtaining it for a long period, the corporation having quite recently succeeded in having the Bill of a private electric light company who proposed to supply it thrown out in the House of Commons. The citizens have much to complain of in this regard. They practically cannot get the modern and clean electric illuminant and they are forced to depend upon a gas mixture the precise nature of which is concealed. The price of this gas has recently been lowered to 3*s*. 4*d*. per 1000 feet, but even this figure does not compare favourably with the expense of gas in other towns.

Coroner for Ballymoney District.

At a meeting of the Antrim County Council held on July 10th Mr. J. C. Woodside of Ballycastle was appointed coroner for the Ballymoney district in the room of the late Dr. Carnac.

The Water-supply of Belfast.

For some time a good deal of discussion has been raised in Belfast in reference to our water-supply, especially as some people believe the present catchment areas may be in part, owing to their contamination, the cause of the present outbreak of typhoid fever, and this has been brought home still more to the public by the fact that the officer of health of the city has publicly advised that all water used for domestic purposes should be boiled. We are promised a new supply from the Mourne mountains, but even in reference to it some curious statements have been made; and hence, to clear up all doubts, an interviewer of one of the city papers has put the whole matter before the chairman of the Works Committee of the Water Board, and as a result a great deal of authentic information has been placed in the hands of the people of Belfast. The reason why the Water Commissioners have built the conduit first and have left the storage reservoirs to be constructed afterwards is that by taking them separately they will save expense, and also because by taking the water direct from the Kilkeel river and the Annalong river, through the help of weirs, a supply of water can be obtained in a short time. The present catchment areas—Woodburn and Stoneyford, which have cost £700,000—give 11,500,000 gallons per diem all the year round, and just now 13,000,000 gallons are the daily consumption. The present wet summer saved matters this year, but another summer cannot be faced without an additional supply, and if the city of Belfast increases as it has done since 1894 in seven years hence 16,000,000 or 17,000,000 gallons per diem will be needed. It is hoped that between April and July from 2,000,000 to 3,000,000 gallons per day may be obtained from these rivers at Kilkeel, and during the other eight months 10,000,000 gallons per diem. Whether there will be such a supply or whether the water will be quite clear of sediment or peat remains to be seen. It is hoped that before the end of this year this supply may be ready for use and for the present this water will be given to residents on the County Down side of the river Lagan which divides Belfast. By this means the strain on the Stoneyford and Woodburn supplies will be relieved, and then when the bridge is built to carry the mains across the river Lagan those living on the County Antrim side will also be supplied. The commissioners also propose to build simultaneously the new reservoirs in the Silent Valley at Kilkeel and the iron bridge across the river Lagan in Belfast; but in the meantime, by means of the conduit and the tapping of the Kilkeel and Annalong rivers, the city will be kept safe as far as a necessary supply of water is concerned. The reservoir dam at Kilkeel will cost a large sum—it may be a quarter of a million—as there is a deposit of sand and drift of unknown depth which will have to be cleared out. When this dam is finished 10,000,000 gallons per diem will come from Kilkeel and it is intended by this supply to add to, but not to supersede, the existing supplies from Woodburn and Stoneyford. When the whole new scheme is finished it will cost about £1,000,000, or about £100,000 per 1,000,000 gallons per day for 10,000,000 gallons of water.

New Medical Magistrate.

Dr. Henry O'Neill, surgeon to the Royal Hospital, Belfast, and a city councillor, has been made J.P. of the county of the city of Belfast.

July 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Cerebellar Abscess.

THIS condition, which is by no means common, was the subject of an important communication made to the Academy of Medicine by Professor Dieulafoy at a recent meeting. In his opinion cerebellar abscess is always consequent upon an otitis. Whether the otitis be acute or chronic and whether there be discharge or not matters little; once the cavity of the tympanum is infected the

organisms can exalt their virulence under most favourable conditions in the closed cavities of the antrum and the mastoid cells. From there they propagate themselves in different directions. The intra-cranial lesions consecutive to the various forms of otitis are many in number, such as cerebro-spinal meningitis, pachy-meningitis, phlebitis and thrombosis of the sinuses, cerebral and cerebellar abscesses. As a rule cerebellar abscess gives rise to the cerebellar group of symptoms, namely, occipital headache, ictus, loss of equilibrium, vertigo, staggering, vomiting, nystagmus, cervical contraction, optic neuritis, muscular asthenia, and a torpid condition bordering upon coma. These symptoms make up the cerebellar *syndrome* in its purity and are found whether the lesion be in the right lobe, in the left lobe, or in the vermiform process. If two other symptoms—namely, facial paralysis and paralysis of the external ocular motor nerve—are present the lesion can be assigned to one in either lobe. This was the case in a patient under the care of Professor Dieulafoy. The cerebellar *syndrome* closely resembles the auricular or labyrinthine *syndrome*. The following are points of difference for the purposes of diagnosis. Labyrinthine headache is not so severe or so persistent nor is it in the same place as that due to cerebellar mischief, while the drowsiness and torpor which increase from day to day in cerebellar mischief do not appear in labyrinthine disease. Abscess of the cerebellum has to be distinguished from abscess of the cerebrum situated in the temporo-sphenoidal or occipital lobes. In a cerebral abscess the motor disturbances, whether paralysis, contraction, or spasm, are situated on the opposite side to the lesion or the otitis, and disturbances of speech and hemianopsia are two important symptoms. Tumours of the cerebellum, such as glioma, gliosarcoma, tubercle, and parasitic tumours, also give rise to the cerebellar *syndrome*, but it is not so well marked in the case of a tumour, owing to the e giving rise to other symptoms attributable to their growth. Cerebellar syphilis stands upon a different plane both as regards diagnosis and treatment. Surgical intervention at the right time is the only treatment for cerebellar abscess. At the same meeting M. Laborde showed various animals, such as cats and guinea-pigs, in which different intra-cerebellar lesions had been brought about. In these the cerebellar group of symptoms was complete—cervical contraction, muscular weakness, and rotation in the long axis towards the same side as the lesion. Experimental reproduction of pathological lesions was thus complete.

Medical Tours to French Mineral Springs.

Last year Dr. Carron of La Carrière organised under the patronage of M. Brouardel, M. Landouzy, M. Cornil, M. Fournier, and M. Huchard a system of tours intended to combine instruction and pleasure and the object of which was to enable medical men and medical students, both French and foreign, to make themselves practically acquainted with the French health resorts. Last year the tour consisted of visits to the places in the central districts and Auvergne. This year the tour will be to the Pyrenees and the south-west districts. Luchon is the starting-place and thence the party will visit Capverne, Bagnères de Bigorre, Argelès, Barèges, Saint Sauveur, Cauterets, Pau, Saint Christau, Eaux Bonnes, Eaux Chaudes, Salies de Béarn, Biarritz, Cambo, the Sanatorium at Hendaye, and Dax and Arcachon. As was the case last year Professor Landouzy, the scientific head of the expedition, will deliver lectures upon the properties of, and the therapeutic indications for, the use of the different places.

Completion of the Faculty of Medicine.

In view of the forthcoming International Congress of Medicine and also the Congress of the Medical Press most of the medical institutions in Paris are getting ready for the reception of visitors. I have already described the hospital alongside of the Pasteur Institute. The new Academy of Medicine will, unfortunately, not be ready in time but the Faculty of Medicine is quite ready. The works have been going on for 23 years and were at a standstill for a space of six years. Work was recommenced in 1898 with the large wing in the Rue Hautefeuille. This is now just open and includes a magnificent vestibule opening upon the interior quadrangle of the faculty and ending at the great staircase of the library. On the first floor are large examination rooms, waiting rooms, and a spacious common room for the different professors. This is ornamented with busts of distinguished physicians and surgeons, while the walls are hung with the magnificent Gobelins tapestry which was presented to the old school of surgery, which occupied the present site of the Faculty of Medicine, by Louis XV. While the works were in progress the architect came across the foundation-stone of the old school of surgery, still bearing its bronze plate upon which were inscribed the details of the former ceremony of inauguration. Only recently, too, a subsidence in the courtyard revealed the cellars of the old Franciscan convent which formerly existed on this site, and the chapel of which, used as an examination room, was only pulled down during the progress of the present works.

Sanitary Instructions for the Troops going to China.

The Minister of Marine has issued an excellent circular for the troops who, in increasing numbers, are daily starting for China. The circular deals with the climatology of Northern China and gives details as to water, food, and other points of vital importance for the well-being of the troops. Next week I shall lay some further details before your readers.

The Culture of Gonococci in Gelatinised Blood.

Everybody knows the difficulties which are experienced in cultivating gonococci in the usual culture mediums employed in the laboratory. A great step in advance has been taken and was described in a report which M. F. Bezançon and M. F. Griffon recently laid before the Society of Biology. These observers found that blood mixed with gelose made an admirable medium for the culture of gonococci. Tubes of this material infected with gonorrheal pus showed at the end of about 24 hours in a temperature of 37° C. numerous round flat transparent colonies of variable dimensions. If these colonies were examined at the end of the first 24 hours the microbes appeared under their characteristic forms and not as misshapen granules as is the case with other methods of culture. The cocci survive for a considerable time and in one tube the observers were able to preserve the organisms alive for a period of six months. This peculiarity, together with the advantages resulting from the early growths of the colonies and the marked morphological characteristics of the microbes which appear by this method, make it an eminently practical one for the culture of this organism.

July 17th.

Obituary.

BENJAMIN HOWARD, M.A., M.D. NEW YORK, M.R.C.S. ENG., F.R.C.S. EDIN.

THE death is announced, in his sixty-fourth year, of Dr. Benjamin Howard of New York. He had been ill for some months, suffering from nephritis. He died at the country house of his old friend, Dr. Andrew H. Smith of Elberon, New Jersey, where he spent the last few weeks of his life. Dr. Howard was born in 1836 and studied medicine in Paris, Vienna, and Berlin, as well as in New York. In 1858 he graduated as M.D. of the University of New York, serving through the Civil War as an assistant surgeon. He afterwards held the posts of professor of surgery and surgeon to Long Island College Hospital, New York State, and of lecturer upon operative surgery in the Medical Department of the University of New York. He was also professor of surgery in the University of Vermont. A frequent visitor to this country, he became a Member of the Royal College of Surgeons of England in 1877 and a year or two later a Fellow of the Royal College of Surgeons of Edinburgh. He was deeply interested in the study of methods for artificial respiration, and having come to the conclusion that there were faults both of omission and commission in the respective methods of Marshall Hall and Silvester he devised a method of his own called the "direct" method, which he demonstrated at a clinical lecture at King's College Hospital on July 7th, 1877.[1]

A supplement to this lecture, giving the method in more detail, was published by Dr. Howard in THE LANCET of May 25th, 1878, p. 748. The outcome of these demonstrations was that a committee of the Royal Medical and Chirurgical Society was appointed to report upon the methods adopted by the Royal Humane Society (which, to put it shortly, combined Marshall Hall's method of removing fluid with Silvester's method of respiration) and that recommended by Dr. Howard. The result of the preliminary report was to show that no one method could be said to be the best, but that a combination of the three would probably be superior to

[1] THE LANCET, August 11th, 1877, p. 194.

any one.[2] Another subject in which Dr. Howard took an abiding interest was that of ambulances for large towns. His attention had been first drawn to the matter when on the battlefield of Antietam he had suddenly become responsible for the ambulance service there. London, as he said in his paper upon the subject read before the Medical Society of London, is a *quasi*-battlefield[3] and needs an efficient ambulance service. 18 years have elapsed and we are but little better off than before in the way of horse ambulances, although owing to Dr. Howard's efforts a meeting was held to consider the matter, when the general hospitals were represented and the Duke of Cambridge was in the chair. Still, at page 119 of our issue of July 14th will be found an annotation stating that a scheme formulated by Mr. S. Osborn, F.R.C.S., for the establishment of an ambulance system for London is before the London County Council. Therefore it seems probable that coincidently with Dr. Howard's death steps are at length being taken to bring about the fulfilment of the object he so ardently desired.

GEORGE SAMUEL GREGORY, M.R.C.S., L.S.A.

MR. BRUDENELL CARTER writes: "The death, on July 9th, in his eighty-eighth year, of Mr. George Samuel Gregory removes from the ranks of the medical profession not only one of its oldest, but also one of its most accomplished members. Mr. Gregory obtained his qualifications in 1835, and, after a period of practice in London, and some time spent in travelling, much of it in Spain during the Carlist war, settled at Pewsey, in Wiltshire, but removed in 1848 to Stroud in Gloucestershire, where he conducted an extensive practice for 35 years and was also certifying surgeon under the Factories Act for the district. He retired in October, 1883, and resided first in Bloomsbury and for the last three years in Kensington, able until the 13th of June to take almost daily walking exercise, and to enjoy the society of his friends. On the 14th of June he suffered from a cerebral hæmorrhage, producing left-sided paralysis, and he passed quietly away on the 9th of July. Mr. Gregory was not only a remarkably skilful and successful practitioner, but was also a man of very unusual attainments in various ways. A fair mathematician, a clever mechanic, a good scholar, and an accomplished linguist, he was deeply read in many directions, especially in dogmatic theology and in the mental philosophy of the earlier portion of the century. He was a learned art critic, an amateur architect of no mean ability, had designed most of the furniture of his pretty house at Stroud, and was a most successful gardener, especially in the cultivation of the cyclamen. A keen observer of men and manners, with a retentive memory and a great command of picturesque and telling language, he was an animated and brilliant talker, and was frequently visited at Stroud by men who had attained celebrity in different walks of life. Wilkie Collins wrote much of "The Woman in White" while staying with Mr. Gregory, and gathered the names of some of the characters from tombstones in neighbouring churchyards. Another of his intimate friends was the late Mr. St. John Mivart, F.R.S., and another was Mr. Frank Dicksee, R.A., some of whose early work still adorns the house at Stroud. Although a bachelor, and not altogether free from a tendency to criticise the foibles of the opposite sex, he was conspicuous for his old-fashioned and graceful courtesy to women, and was a very general favourite with them. There could perhaps be no better evidence of his sterling and loveable character than the fact that among those who stood around his grave there were three men of different callings who were united to him by ties of close and uninterrupted friendship which had existed, in the case of the writer for 38, in another for 48, and in the third for 60 years."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. James T. Whittaker, Professor of Medicine in the Ohio Medical College, Cincinnati.—Dr. A. Schetelig of Nervi, whose researches on archæological subjects are well known. He was in early life assistant to Professor Esmarch of Kiel and during the Franco-German war was in charge of the Hamburg Red Cross Ambulance at Metz.

[3] THE LANCET, Feb. 4th, 1882, p. 172.

Medical News.

UNIVERSITY OF OXFORD.—The following candidates at examinations for the degree of Bachelor of Medicine, Trinity Term, were successful in the subjects indicated:—

FIRST EXAMINATION.

1. *Organic Chemistry.*—George Basil Doyne Adams, Christ Church; Owen Alfred Rowland Berkeley-Hill, Trinity College; George Henry Crosfield and Turner Henderson, University College; Reginald Jamison, Trinity College; William Herbert Lee, Balliol College; Cuthbert Taunton Raikes, Trinity College; and Charles Joseph Singer, Magdalen College.
2. *Materia Medica and Pharmacy.*—Launcelot Toke Burra, University College; Edward Burstal, Trinity College; Henry Roy Dean, New College; Gerald Edward Friend, Keble College; Reginald Charles Jewesbury, Christ Church; James Edmund Rutherfurd, Corpus Christi College; Arnold Shelley, Keble College; Charles Joseph Singer, Magdalen College; and Cyril Aubrey Smallhorn, Wadham College.
3. *Human Anatomy and Human Physiology.*—Philip Edward Homer Adams, Exeter College; Edward Frederic Beaumont,* Wadham College; John Martin Bickerton, Merton College; Walter Brinsmead Billinghurst, St. John's College; William Edward Blackall,* non-collegiate; William Leigh Maule Day, Exeter College; Harold Frankish, Worcester College; Arthur Frederick Hertz, Magdalen College; Dudley William Carmalt Jones, Corpus Christi College; Henry Wynyard Kaye, Magdalen College; Harold Lionel Laws, Wadham College; Richard Ernest Howell Leach, Merton College; Douglas Reginald Pike,* Jesus College; James Edmund Rutherfurd, Corpus Christi College; and Richard Harvey Sankey, Christ Church.

* Offer Human Anatomy only, being exempt from examination in Human Physiology.

SECOND EXAMINATION.

1. *Pathology.*—Arthur Edwin Boycott, B.A., Oriel College; Lawrence Henry Carr-Birkbeck, B.A., Trinity College; William Morris Gladstone Glanville, B.A., Christ Church; Edmund Henderson Hunt, B.A., Balliol College; Alfred Edward Arthur Loosely, B.A., Pembroke College; Reginald Cuthbert Mullins, B.A., Keble College; Lionel James Picton, B.A., Merton College; and Charles Ernest West, B.A., Balliol College.
2. *Remaining Subjects.*—Edmund Delafosse Bond, B.A., and Reginald Cuthbert Mullins, B.A., Keble College; John Davy Rolleston, B.A., Brasenose College; Albert Edward Thomas, B.A., Merton College; and Richard Warren, B.A., New College.

UNIVERSITY OF GLASGOW.—The following candidates have passed the final examinations for the following degrees:—

M.B., C.M.—John Lunn, Alexander M'Donald Nevin, John James Robertson, James Wallace Shane (old regulations), and Archibald Stevenson.

M.B., Ch.B.—Matthew Aikman, M.A., George Arthur, Gavin Barbour, Thomas Thomson Bathgate, James Freeborn Bennett,‡ Alexander Binning, Alexander Birch, Harry Egerton Brown, John Douglas Brownlie, Thomas Carruthers, M.A., Alexander Henderson Cassells, Edward Provan Cathcart,‡ Daisy Annabella Murdoch Clark, B.Sc., John Thomson Clark,‡ Robert Clark, Charles Campbell, Cuthbert, M.A.,† Archibald William Wallace Davidson,‡ Frank Lindsay Dickson, David Curr Douglas, John Pinkerton Duncan, B.Sc.,† Leonard Findlay,*† Alexander Fraser, M.A., Lizzie Thomson Fraser, Gilbert Garrey, David George Somerville Gartshore, William Gibson, Edward Gillespie, William Girvan, Helen Mary Gordon, Charles Aikman Gourlay, M.A.,‡ John Gracie, Charles Herbert Gunson, Archibald Wilson Harrington,‡ Isaac Mackay Huey, Thomas Inglis, Pierce Jones, William Bryce Kerr, James Dickson Laidlaw,* John Francis Lambie. Norman Maclean Leys,‡ James Dunlop Lickley,‡ Mary Forbes Liston, John Lockhart, Alexander Logan, David Longwill, Anderson Gray M'Kendrick,‡ James Mackinnon,‡ George Todd Maclean, M.A., Alfred Robert Maclurkin,‡ Burgess M'Phee,‡ Andrew Mair, Robert MacNab Marshall,‡ Allan Martin, M.A., B.Sc.,‡ James Millar, M.A., Ernest Wardlaw Milne, Alexander Robert Moir, Alexander Munro, William Barr Inglis Pollock, Robert Rennie, John Duncan Richmond, Margaret Mitchell Ritchie, David Russell, James Scott, M.A., Edgar William Sharp, James Shearer, David Ap Simon, Christian Cleland Wood Smith, James Johnston Smith, John Steele Smith, Andrew Stewart, Gertrude Florence Fleetwood Taylor, Robert Taylor, Thomas Bird Tierney, James Cameron Turnbull,† William Dinning Walker, George White, Morgan Watkin Williams, Alexander Wilson,*‡ Thomas Watson Wilson, and Hugh Patrick Wright.‡

* Surgery and Clinical Surgery.
† Practice of Medicine and Clinical Medicine. ‡ Midwifery.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore:* Dr. F. S. Cullen and Dr. W. W. Russell have been appointed Professors of Gynæcology in the Johns Hopkins University.—*Jena:* Dr. Friedrich Schultz has been promoted to an Extraordinary Professorship of Physiological Chemistry.—*Marburg:* Dr. Axenfeld of Rostock has been offered the chair of Ophthalmology.—*Montpellier:* Dr. Bosc has been appointed to the chair of Pathological Anatomy.—*St. Petersburg* (*Military Medical Academy*): Dr. A. Gerwer has been recognised as *privat-docent* of Neurology and Psychiatry.—*Strasburg:* Dr. Edwin Faust has been recognised as *privat-docent* of Pharmacology.—*Vienna:* Dr. Gustav Braun von Fernwald, Director of the Third Midwifery

and Gynæcological Clinic, a brother of the well-known gynæcologist, Professor Karl Braun, is about to retire, having reached his seventy-first year.

WATER CARRIAGE.—It is not often that attempts are made to go back to the old methods of dealing with excreta, but at a recent meeting of the Manchester City Council an alderman proposed the following motion:—"That in considering the plans of new buildings the Improvement and Buildings Committee be instructed not to insist upon the provision of water-closet accommodation, unless special circumstances render it desirable." His idea was that water should be carefully used until the laying of the second pipe from Thirlmere is completed, which will take three years. It was stated, however, that the effect of the present water-closet system on the water-supply was not appreciable. The motion was rejected.

THE HEATH SCHOLARSHIP.—The Heath Scholarship, value £200, which is awarded every two years by the University of Durham, has this year been awarded to Dr. Nathan Raw of Liverpool, and Major J. R. Dodd, R.A.M.C. The subject of the essay was, "The Urinary Tract, its Injuries and Surgical Diseases, their Pathology, Diagnosis, and Treatment."

THE ROYAL VETERINARY COLLEGE.—The Duke of Cambridge presided at the annual meeting of the Royal Veterinary College, of which he is president, on July 11th. The twenty-fifth annual report showed that during the financial year 1899-1900 59 students had entered the college, as compared with 66 last year. At the examinations held by the Royal College of Veterinary Surgeons in July last 73 per cent. of the students presenting themselves proved successful, while at the December examinations 66 per cent. passed. 70 per cent. of the 226 students of the college who presented themselves for examination during the year passed, while 66 per cent. of the 244 students who presented themselves for the same examination from the other veterinary colleges were successful. During the year 43 students obtained the diploma of the Royal College of Veterinary Surgeons, 32 students succeeded in passing the first professional examination, 43 the second, and 40 the third. In the research department complete or partial post-mortem examinations in 355 cases of disease had been made for members of the Royal Agricultural Society and for veterinary surgeons. The gratuitous supply of mallein to veterinary surgeons in private practice had been continued and the manufacture of tuberculin was begun in the early part of last year with a view of supplying the requirements of qualified members of the veterinary profession. The chairman of the governors, Sir Nigel Kingscote, stated that two investigations were being made at the college, one with regard to the reliability of tuberculin as a test for tuberculosis, towards which the Royal Agricultural Society had made a grant of £400, and the other into the cause of African "horse-sickness," towards which the War Office had given £200. Lord Egerton of Tatton was elected a vice-president in place of the late Duke of Westminster, and Lord Moreton and the Hon. W. F. D. Smith, M.P., were appointed governors.

ST. MARY'S HOSPITAL.—PRIZE AWARDS.—On July 13th Dr. T. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge, distributed the prizes won by the students of St. Mary's Hospital. Dr. W. B. Cheadle presided.—Dr. H. A. Caley (the Dean), who read the report, which referred to the reconstitution of the University of London, said that the medical school had become one of the first schools of the London University. The medical school had upwards of 50 representatives with the Imperial forces in South Africa, and they had to deplore the deaths of Captain R. H. E. G. Holt, R.A.M.C., from wounds, and of Lieutenant G. W. G. Jones, R.A.M.C., from enteric fever, in Ladysmith, as well as of Lieutenant-Colonel A. Baird Douglas, a former student of the school, who was killed while in command of the 4th Battalion Sherwood Foresters at Roodeval. The record of academic distinctions for the year was high, notably at the University of Cambridge. In athletics the students had been remarkably successful. Important advances in the pathological department had been made during the year.—Professor Allbutt in distributing the prizes said that though Ruskin had said that the great achievement of modern education had been to teach people to think wrongly on every conceivable occasion he did not think that this applied to the education of the end of the nineteenth century. Nowadays students were taken through natural phenomena and taught to observe and to think, and the result was seen in the excellent work brought forward at examinations. There had been an extraordinary improvement in teaching and in the accessibility of knowledge, the tendency being to take the student away from the lecture-room into wards and laboratories. The process of verification thus instituted was most useful and was happily gaining ground.—On the motion of Sir W. Broadbent a vote of thanks was accorded to Professor Allbutt, and the usual courtesies to the chairman terminated the proceedings.

THE Victorian Convalescent Home for Surrey Women and the Duchess of Teck Memorial Home of Rest for Working Women were opened by the Duchess of York at Bognor on Monday, July 9th. The buildings are in the Renaissance style of architecture and fitted up according to the most modern improvements of sanitary science. The Victorian Convalescent Home is Surrey's memorial of Her Majesty's long and glorious reign, while the Duchess of Teck Memorial Home of Rest for Working Women is the nation's memorial to the late Princess Mary.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 17TH.

The Question of Death Certification.

LORD MONKSWELL called the attention of the Government to the report of the Select Committee of the House of Commons on Death Certification and asked whether they proposed to introduce legislation on the lines of the recommendations of the committee.—Lord HARRIS, replying for the Government, said that for some time the subject had engaged the attention of the President of the Local Government Board with a view to legislation. There were, however, a good many difficulties connected with it and Mr. Chaplin was at present having inquiry made by the officers of the department in the hope of overcoming these difficulties. Mr. Chaplin was in hopes that at no distant date he would be able to introduce a Bill on the subject.

HOUSE OF COMMONS.

THURSDAY, JULY 12TH.

Anti-typhoid Inoculation.

MR. BARTLEY asked the Under Secretary of State for War whether his attention had been called to a report from Dr. Conan Doyle on the Langman Hospital, South African Field Force, Bloemfontein, in which he stated that there had been no death from enteric fever up to June 5th from among the inoculated; whether the War Office had yet any official statistics on the results of inoculation; and whether any further efforts were being made to increase the number inoculated in men now going out to South Africa and China.—Mr. WYNDHAM replied: As I have already explained to the House the statistics at present available are not sufficient to enable me to give a reply to the first and second paragraphs of the question. Inoculation is offered to all men embarking from home for a country such as South Africa or China where enteric fever is prevalent, but such inoculation is purely voluntary.

FRIDAY, JULY 13TH.

Medical Acts Amendment Bill.

The Bill to strengthen the disciplinary powers of the General Medical Council to give universities and medical corporations power to withdraw their diplomas from practitioners whose names have been removed from the Medical Register because of misconduct, and to provide that fines and penalties recovered under the Medical Acts shall be paid to the treasurer of the General Medical Council, was introduced at this sitting by Sir Richard Jebb and formally read a first time, the order for the second reading being put down for Thursday, July 19th. The Bill is backed by Sir Richard Jebb, Sir William Anson, Mr. J. A. Campbell, Sir Michael Foster, Mr. Lecky, Mr. Talbot, and Sir John Batty Tuke, all of whom are university representatives.

Oil in Manufactured Tobacco.

The Chancellor of the Exchequer introduced a Bill to restrict the amount of oil in manufactured tobacco.

The Employment of Retired Army Medical Officers.

Mr. MACNEILL asked the Under Secretary of State for War if he could state what was the number of the retired army medical officers who were liable to be recalled to service, and of these gentlemen how many had been recalled to service since the outbreak of hostilities in the Transvaal, and how many were now with the field forces in South Africa or in hospitals at the bases.—Mr. WYNDHAM replied: There are 98 retired army medical officers liable to recall; of these 18 are holding permanent appointments reserved for officers on retired pay. The services of 25 others who volunteered to return to the service have been accepted and they have been employed at home and abroad. None have been recalled by compulsion. Four officers are employed in South Africa and on hospital ships.—Mr. MACNEILL asked: Then out of 98 officers on the retired list only four are employed in South Africa?—Mr. WYNDHAM replied: Yes. The 18 who are holding permanent appointments are officers of high rank and it is thought better to employ in South Africa young civilian doctors who have more recent experience of hospital work.

Lead and Phosphorus Poisoning.

These subjects were discussed at this sitting in Committee of Supply on the vote for the Home Office. Sir MATTHEW WHITE RIDLEY, in the course of his reply, said that with regard to lead poisoning in the earthenware manufactories in the Potteries although the improvement had been steady and substantial it had not been all that they could wish. Whether the figures were good or bad the fact remained that lead poisoning in the Potteries was a fearful thing and far more serious than phosphorus poisoning. He was, therefore, prepared to admit, on the part of the Home Office, that the case demanded the most urgent attention, and on their part they should do everything that they possibly could to secure that the industry should be carried on in a manner as little harmful as possible to those engaged in it. They had not been altogether idle in this matter. He admitted to the full that the existing code of rules was not sufficient, but it had done a considerable amount of good. They had been engaged on a new code of rules which would shortly be published and which he hoped would carry out substantially everything recommended by Dr. Oliver and Dr. Thorpe, with the exception that there was no absolute prohibition of the use of raw lead in every case. He had every hope that the rules would be accepted and he was almost confident that they would get them without arbitration, but he should go to arbitration rather than that the present state of things should continue. With reference to the case of the phosphorus special rules, which had already been debated this session, he was very much astonished to find that so many members took the view that the rules had really not been strengthened. There were one or two points in which the rules were weakened contrary to their desire, but he claimed for them in the first instance that they were drawn up in the main to carry out the recommendations of their experts. They were to a certain extent altered, but if those alterations were minutely examined it would be found that they were not really of that importance which some members attached to them. He did not know if he needed to go into them in detail, but to take, for instance, the distinction between the wet and the dry process. He could not say they were in a position to decide that they had the same positive evidence in regard to the injury in the one case as they had in the other. He was not prepared to admit that the rules regarding the matchmaking industry were weak or that they were not a considerable improvement upon the rules passed some years ago. There again he did not see how it was possible to prohibit absolutely the use of this particular kind of phosphorus. As the result of what had been done there had only been one case of necrosis reported in the past six months and the department had, to a large extent, got hold of the disease. The effect of the attention paid by manufacturers to the new process was that one large firm had abandoned altogether the use of dangerous phosphorus; and if it was possible to supply strike-anywhere matches as cheaply without the use of this dangerous stuff the public could do a great deal in encouraging its disuse. With regard to an international arrangement to do away with the use of white and yellow phosphorus, he feared that there was not much hope of it. As to the phosphorus trade, he hoped that those who had criticised the rules would test them by experience. If there were a loophole in them further action could be taken.

MONDAY, JULY 16TH.

Civil Surgeons in South Africa.

Mr. MACNEILL asked the Under Secretary of State for War if he could state the number of civil surgeons whose services had been accepted since the outbreak of hostilities in South Africa for the field hospitals and base hospitals, and the number of civil surgeons who were at present employed in these hospitals, and how many army medical officers within two years from their entrance into the Army Medical Service had been sent to the war in South Africa; whether his attention had been drawn to the fact that of 98 army medical officers who were liable to be recalled to service four only were employed in South Africa or in hospital ships, and that although many of them have requested to be sent to the seat of war their offers were refused; whether the authorities at the War Office were aware that the sending of army medical officers without previous experience in campaigns, and the recognition of the services of civil surgeons while the services of retired army medical officers had been rejected, had led to discontent and a feeling that the medical treatment of the troops would be wholly subordinate to purely military considerations; and would he cause inquiries to be made in the matter.—Mr. WYNDHAM replied: The services of 385 civil surgeons have been accepted principally for base hospitals and general duty; of these 363 are now in South Africa. This does not include those locally employed or attached to private hospitals or to the Yeomanry or the Rhodesian Field Force. 117 Royal Army Medical Corps officers under two years' service have been sent out. Of the 98 officers liable to recall, as has been already stated, 18 hold permanent military appointments at home, and very few volunteered for service in South Africa Nothing is known of any general discontent to which the honourable gentleman refers in his question.

A Vaccination Case.

Mr. SINCLAIR asked the Home Secretary whether he was aware that Mr. F. J. Chatting was imprisoned for not paying a fine for non-compliance to an order for vaccination; that the warrant for his arrest was for Pentonville, but that he was taken to West Ham Police-station, then taken to Stratford Police-court, and kept without food from 8 A.M. to 8 P.M. on July 7th; and that on his arrival at Pentonville, instead of being treated as a first-class misdemeanant, his clothes were taken from him, and that he was forced to wear a prison suit, and that he was subjected to other treatment which the Act did not permit; and whether he would take such steps as would prevent a recurrence of such proceedings.—Sir MATTHEW WHITE RIDLEY replied: Chatting was not arrested till about 8.40 P.M. on the 6th. It was then too late to take him to Pentonville, so he was taken to West Ham Police-station and thence on the next morning to the police-court in accordance with the usual practice in order that he might go on to Pentonville by the afternoon van. He had breakfast at the station and might have had lunch at the police-court, but on being twice asked whether he wanted anything replied in the negative. At Pentonville the reception officer made a mistake and treated him like an ordinary prisoner. For this mistake he will be duly dealt with by the Prison Commissioners and it is not one which is likely to recur.—Mr. SINCLAIR: As I understand that no compensation will be paid to Mr. Chatting will some apology be offered to him?—Sir MATTHEW WHITE RIDLEY replied: I have not considered any question of compensation.

Hospital Provision in Scotland.

Mr. WEIR asked the Lord Advocate whether the Secretary for Scotland was aware that the medical officer of health for Ross and Cromarty in his report for last year stated that, in a township in the island of Lewis there were 41 cases of typhoid fever in a population of 300 within a period of six months and pointed out that, although an isolation hospital was urgently necessary the local authorities were powerless to provide one owing to the rates for the various parishes throughout the island being already so high; and in view of the insanitary condition of many of the parishes in the island would he consider the expediency of either urging the Treasury to provide the requisite funds for the erection of an isolation hospital or introduce legislation at an early date such as will admit of the Congested Districts Board applying a portion of the funds at its disposal for the erection and maintenance of isolation hospitals where urgently needed in the congested area.—Mr. WEIR further asked the Lord Advocate whether he was aware that the report of the medical officer showed that if the sanitary clauses in the Public Health (Scotland) Act were strictly enforced in the island of Lewis a large number of the inhabitants would be homeless; and could he state what steps he proposed to take in order to place the island on a satisfactory sanitary basis.—The LORD ADVOCATE replied: As to the sanitary condition of the island of Lewis, I must point out that the enforcement of the new provisions of the recent Public Health Act can be undertaken only gradually and with caution, both for the reason adduced by the hon. Member himself and because of the reluctance which he must know exists in the Highlands to removal and to isolated treatment of infectious cases. The Local Government Board are not inactive and I know from official and other channels that progress is being made, and that in some districts the present conditions compare very favourably with those observed not many years ago. I am informed by the Local Government Board that they are at the present moment in communication with more than one local authority in the island districts regarding new hospital accommodation, and plans are in hand for an hospital in the Carloway district. The Secretary for Scotland is not prepared at present to undertake legislation in connexion with the matter.

The Lunacy Bill Withdrawn.

The Bill of the Government for the reform of the Lunacy Laws, which had passed through all its stages in the House of Lords, was at this sitting of the House of Commons withdrawn.

TUESDAY, JULY 17TH.

The South African Commission.

Mr. BALFOUR announced that Mr. Harrison, general manager of the London and North-Western Railway Company, and Sir David Richmond, ex-Lord Provost of Glasgow, have agreed to serve on this commission in addition to Lord Justice Romer, Dr. Church, and Professor Cunningham.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BERTHON, ELLEN M. T., M.B. Lond., has been appointed a Locum Tenent by the St. Pancras Board of Guardians.

BRISCOE, WILLIAM THOMAS, A.B., M.D., M.Ch. Dubl., has been re-appointed Medical Officer of the Pewsham District by the Chippenham Board of Guardians.

BUCHANAN, R. J. M., M.D. Vict., M.R.C.P. Lond., has been appointed Honorary Physician to the Liverpool Stanley Hospital, vice C. J. Macalister, retired.

EMANUEL, J. G. M.B., B.S., B.Sc. Lond., has been appointed Pathologist to the General Hospital, Birmingham.

GRIFFITHS, CORNELIUS A., F.R.C.S., has been appointed Honorary Assistant Surgeon to the Cardiff Infirmary, vice W. Sheen.

HAWTHORNE, C. O., M.D., M.R.C.P., has been appointed Physician to the Central London Ophthalmic Hospital, Gray's Inn-road, W,C.

MEACHEN, G. NORMAN, M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Tottenham Hospital, N.

NEWINGTON, C. W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Sixth Sanitary District of the Sevenoaks Union, vice C. F. Gregory.

PECK, HERBERT, M.D., D.P.H., has been appointed Medical Officer of Health to the Borough of Chesterfield, vice H. Meredith Richards.

PRANCE, C. H. G., L.R.C.P. Lond, M.R.C.S., has been appointed Medical Officer to the Workhouse and No. 1 Sanitary District, Plympton, and Public Vaccinator.

TROTTER, ALEX., M.D. St. And., L.F.P.S. Glasg., has been appointed House Surgeon to the Perth City and County Royal Infirmary.

WARDALE, J. D., M.B., B.S. Durh., has been appointed Honorary Ophthalmic Surgeon to the Royal Infirmary, Newcastle-upon-Tyne, vice G. E. Williamson, F.R.C.S.

WATTS, ELIZA T., M.B. Lond., has been appointed a Locum Tenent by the St. Pancras Board of Guardians.

WHITE, ANTHONY A. T., M.R.C.S., L.R.C.P., has been appointed by the Egyptian Government Medical Officer to the Directeur Générale des Reservoirs, Assouan District.

WILSON, H. C., L.R.C.P. Irel., L.F.P.S. Glasg., has been appointed Medical Officer for the South Sanitary District of the Poplar Union, vice W. M. Leslie, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEDFORD COUNTY HOSPITAL, Bedford.—House Physician for six months. Salary £25 for that period, with board, lodging, and washing.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £150 per annum, with an allowance of £30 yearly for cab-hire, with furnished rooms, fire, lights, and attendance.

BOROUGH ASYLUM, Portsmouth.—Junior Assistant Medical Officer. Salary £120 per annum, increasing by three equal increments up to £150, with board, lodging, and washing.

BRADFORD ROYAL INFIRMARY.—House Physician for 12 months, unmarried. Salary £100 per annum, with board and residence.

BRECON INFIRMARY, No. 6, Bulwark, Brecon, South Wales.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas.

BRISTOL EYE HOSPITAL.—Locum Tenens for the House Surgeon for two months. Salary 2½ guineas a week, without residence.

CARDIFF INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £75 per annum, with board, washing, and apartments.

CARLISLE DISPENSARY (not provident).—House Surgeon. Salary £150 per annum, with apartments (not board).

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Annual re-appointment, but tenable for three years. Honorarium 20 guineas per annum.

CHESTER GENERAL INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with residence and maintenance in the house.

CITY ASYLUM, Gosforth, Newcastle-upon-Tyne.—Assistant Medical Officer, unmarried. Salary £130 a year, with furnished apartments, board, &c., and rising £10 per annum up to £150.

CITY OF LEEDS, BECKETT-STREET FEVER HOSPITAL.—Resident Medical Officer. Salary £130 a year, increasing £10 annually to £150, with board, lodging, and washing. Applications to the Medical Superintendent, Manston Hospital, Seacroft, near Leeds.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising £10 annually to £150, with board, furnished apartments, &c.

CORPORATION OF BIRMINGHAM.—CITY HOSPITAL, Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £100, with board, residence, and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

DURHAM COUNTY ASYLUM, Winterton, Ferryhill.—Assistant Medical Officer. Salary £140, rising £10 annually to £160, with board, laundry, and attendance.

GENERAL LYING-IN HOSPITAL, York-road, Lambeth.—House Physician for four months. Salary at the rate of £50 per annum, with board and residence.

HORTON INFIRMARY, Banbury.—House Surgeon and Dispenser. Salary £80 per annum, with board and lodging.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY, 74, King-street, South Shields.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

ITALIAN HOSPITAL, Queen-square, Bloomsbury, London, W.C.—House Surgeon. Salary £60 per annum, with board and residence.

JENNER INSTITUTE OF PREVENTIVE MEDICINE, Chelsea-gardens, London.—Assistant Bacteriologist to the Antitoxin Department at Sudbury, Harrow. Salary £200 per annum, with rooms.

LIVERPOOL DISPENSARIES, 34, Moorfields, Liverpool.—Four Assistant Surgeons, unmarried. Salary £100 per annum, with board and apartments.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence in the Infirmary.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Assistant Medical Officer to the Out-patient Department, Hardman-street, Manchester. Honorarium £40 per annum.

NORTHAMPTON GENERAL INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with furnished apartments, board, attendance, and washing.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-upon-Trent.—House Surgeon. Salary £120 per annum, increasing, conditionally, by £10 a year, with furnished apartments, board, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—Junior House Surgeon for one year. Salary £75, with board, residence, and washing.

PARISH OF SLEAT.—Medical Officer and Public Vaccinator. Salary £100 per annum. Applications to the Chairman, F. C. Manse, Sleat, Broadford, N.B.

ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £50 per annum, with residence, board, and washing.

ROYAL NATIONAL HOSPITAL AT VENTNOR.—Clinical Assistant. Salary £40, with board and residence. Apply to the Secretary, London Office, 34, Craven-street, Strand, W.C.

ROYAL SOUTHERN HOSPITAL, Liverpool.—Resident Locum House Surgeon for one month. Terms 3 guineas weekly.

SALOP INFIRMARY, Shrewsbury.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board and washing.

SHEFFIELD UNION WORKHOUSE INFIRMARY.—Junior Assistant Medical Officer for the Workhouse Infirmary, Fir Vale, Sheffield, for one year, unmarried. Salary £50, with furnished apartments, board, and washing.

STAMFORD-HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington.—Assistant Resident Medical Officer. Salary £100 per annum, with board.

STATE OF SARAWAK, BORNEO.—Medical Officer for this Government, unmarried. Will be required to sign an agreement for three years. Salary $3600 (about £360) per annum, with free unfurnished quarters. Applications to Messrs. the Borneo Company, Sarawak Government Agents, 28, Fenchurch-street, London, E.C.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing. In lieu of stimulants or mineral waters £6 per annum will be given.

THE Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1897, for the Leith District of the Sheriffdom of the Lothians and Peebles.

TOTTENHAM HOSPITAL, N.—House Surgeon for six or 12 months. An honorarium at the rate of £20 per annum given, with board, residence, and laundry.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Assistant House Physician for six months. Honorarium at the rate of £75 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

GILLETT.—On June 30th, at Brooke, Norfolk, the wife of George Edward Gillett, M.R.C.S., L.R.C.P., of a daughter.

MACKAY.—On July 17th, at Castlegate, Berwick-upon-Tweed, the wife of William Bertie Mackay, M.D., M.R.C.S., of a daughter.

MATHESON.—On July 12th, at 72, Trafalgar-road, Greenwich, the wife of John Matheson, M.A., M.B., C.M., of a daughter.

PRAKE.—On July 14th, at The Limes, Marden, Kent, the wife of W. Harland Peake, M.D., B.S., of a daughter.

QUINBY.—On July 13th, at West View, Formby, Lancs., the wife of Edward M. Quinby, M.R.C.S., L.R.C.P. Lond., of a daughter.

SALISBURY.—On July 11th, at Evering-road, Stoke Newington, the wife of C. R. Salisbury, L.R.C.P, M.R.C.S. of a daughter.

SHAW.—On July 11th, at New Cavendish-street, Cavendish-square, W., the wife of John Shaw, M.D. Lond., M.R.C.P. Lond., of a son.

SINCLAIR.—On July 9th, at Cranbourne, Westerfield-road, Ipswich, the wife of Walter W. Sinclair, M.B., of a daughter.

SMITH.—On July 17th, at 229, High-street, Watford, the wife of G. Francis Smith, M.R.C.S., L.R.C.P. Lond., of a son.

STEAD.—On July 3rd, at Moor Lodge, Hawkhurst, the wife of C. C. Stead, M.B. Camb., L.R.C.P. Lond., of a daughter.

SWAIN.—On July 11th, at Victoria-square, Clifton, Bristol, the wife of James Swain, M.S., M.D. Lond., F.R.C.S., of a son.

MARRIAGES.

EDEN—BAIN.—On July 18th, at St. Mary Abbots', Kensington, by the vicar, the Rev. Canon Pennefather, assisted by the Rev. G. T. Harvey of Navenby, Thomas Watts Eden, M.D., M.R.C.P., to May, only daughter of Mrs. Bain, and granddaughter of the late Sir James Bath of Glasgow.

GOUGH—LONGSTAFFE.—On July 17th, at SS. Mary and John Church, Oxford, by the vicar, Rev. W. Scott, assisted by the Rev. W. D. Macray, rector of Ducklington, Bernard Bradly, son of Henry Gough, barrister-at-law, of Redhill, to Annie S., second daughter of Mrs. Longstaffe, of Oxford.

HENTSCH—PETERKIN.—On Thursday, the 12th inst., at St. Stephen's, Paddington, by the Rev. W. E. Burkitt, B.A., rector of Buttermere, Wilts, George Frederick Hentsch, L.R.C.P. Lond, M.R.C.S., younger son of the late George Hentsch of Chancery-lane and Barnsbury, to Beatrice M., youngest daughter of William Peterkin of Clitheroe, Lancashire.

WALDO—EXTON.—On the 14th July, at the parish church, Hampstead, by the father of the bride, Frederick Joseph Waldo, M.D., barrister-at-law, to Marion, elder daughter of the Rev. R. B. L. Exton, formerly vicar of Strood, Kent.

DEATHS.

GLAZEBROOK.—On July 14th, at Haymans-green, West Derby, Liverpool, Nicholas Smith Glazebrook, M.R.C.S., in his 87th year.

HEYCOCK.—On the 9th instant, at Hounslow, Francis Raworth Heycock, M.D., F.R.C.S., second son of the late Rev. C. Heycock, J.P. of Pytchley House, Kettering, aged 58 years.

LAKE.—On July 18th, at Bloemfontein, W. Wellington Lake, Militia Medical Staff, of Topcroft, Guildford, aged 46 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"SAD DEATH AT MARHAMCHURCH."

UNDER the above title the *Western Morning News* of July 14th prints the following story:—

> Mr. D. Thompson, county coroner, held an inquest at Marhamchurch on Thursday on Selina Matthews, wife of a farm labourer, who died on Wednesday morning. James Matthews said his wife, 30 years of age, was confined of her fifth child on Monday night. She was attended by an "occasional" nurse, and had no doctor. After her confinement she complained of her head, and he went to Mr. Braund on Tuesday afternoon and got some medicine, but did not ask him to visit her. She took some medicine and afterwards for a while was cheerful, but then became drowsy and never rallied, dying on Wednesday morning. She was very sick. Her sister was with her on Tuesday and the neighbours looked in.—The Foreman (Mr. Greenaway): Is it usual for a medical man to supply medicine to patients without seeing them?—The Coroner: It is not unusual. If medicine only is applied for he would do the best he could without a visit. Of course, if asked to see a patient he would not supply medicine until he had first seen the patient.—Mr. Greenaway thought it unusual and would have liked to have heard whether the effects of the medicine given were such as were expected.—The Coroner offered to adjourn the inquest to procure medical evidence, but the jury thought it not necessary.—Mary Ann Cowling, the occasional nurse, said all went satisfactorily. When deceased complained of her head witness recommended sending for a doctor. She was slightly convulsed just before her death.—Emily Jones, a neighbour, said she saw the deceased daily and did not anticipate any danger. She seemed pretty well on Tuesday night, but still complained of her head. On Wednesday morning she was heavy and drowsy and did not speak. She then considered her condition alarming and asked that a doctor be sent for. One was sent for, but death took place before his arrival.—The jury returned a verdict of "Death from natural causes—failure of the heart's action after convulsions."

We cannot agree with the jury that it was unnecessary to hear medical evidence in this case. In the interests of the medical man the jury should certainly have ascertained (1) what the husband told Mr. Braund that his wife was suffering from and (2) what Mr. Braund felt himself able to prescribe under the circumstances. We agree with the foreman that to give medicine to a patient who is not visited is unusual and we may add that as a rule it is very inadvisable; but we do not say that it was inadvisable in this case because we have no notion what the husband said. The "occasional" nurse who said that "all went satisfactorily," might also have been asked what significance she attached to the word "satisfactorily" and under what circumstances she was in the habit when occasionally nursing of sending for medical assistance.

"THE EVER-READY ELECTRIC LIGHT."

To the Editors of THE LANCET.

SIRS,—We notice in THE LANCET of July 14th (p. 111) a description of the "Ever-Ready" Electric Light which Mr. Dale states is made by him. We should very much like to know if he is the manufacturer as we can supply the identical article which is made in America. We beg to hand you a drawing which you will see is the same in every way.

We are, Sirs, yours faithfully,

London, July 17th, 1900. ARNOLD AND SONS.

*** The drawing sent to us by Messrs. Arnold and Sons is undoubtedly identical with that which we published last week. Mr. Dale will, perhaps, state whether he is the inventor or maker. We certainly supposed one or other to be his position.—ED. L.

A QUESTION OF LIABILITY.

AN interesting point was raised in a case which came before Judge Stonor on July 10th at Brompton. A surgeon dentist had rendered professional services to one of the students at the hospital to which he was attached. The latter was under age at the time, and had since joined the troops in South Africa, leaving his dentist's account unpaid. The action in question was for the recovery of 16 guineas from the young student's father, who is a medical man. The plaintiff said that had he charged his usual fees the account would have amounted to £36, and that he made the reduction because the young fellow had studied under him at the hospital. The student, it was stated, always said that his father would pay the dentist's fees, and about a year later the account was accordingly sent in to the father. The latter returned the account repudiating liability; and, in the course of correspondence, said that his son appeared to have been under the impression that a surgeon, medical man, or dentist would not as a rule make any charge when attending a medical student, especially when both, as in the present instance, were connected with the same hospital. The father went on to remark that the fees seemed to be rather high, and asked to be favoured with the views of the dentist as to payment by students in such cases. In another letter the father stated that he had consulted certain hospital authorities, and that they had advised him not to pay the account. The plaintiff, in his evidence, stated that he distinctly told the young fellow that he could not afford to attend the students at the hospital free of charge. His Honour said it was evident that the student had pledged his father's credit, but there was some doubt as to the father's liability. Counsel for the plaintiff maintained that the attendance in question was necessary to the young fellow's health, and that the father was therefore liable. Counsel for the defence contended, on the other hand, that if the son had been living with his father at the time that the services were rendered, there might have been something in the submission of the plaintiff's counsel, but as a matter of fact the son was in lodgings at the time. The learned counsel went on to contend that as the plaintiff had not the defendant's authority to render the services, the latter was not liable. His honour said he was not convinced that the attendances in question came under the heading of necessities within the meaning of the Acts relating to the point. There was evidence that the student pledged his father's credit, but there was no evidence that the father gave him authority to do so. This being so, his Honour found that the defendant was not liable. The case was struck out, no costs being allowed.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Could any of your readers inform me of a medical man residing in a small seaside place or in the country about North Wales or in the north of England or some quiet place over 100 miles from London, who would be willing to receive into his house a lady subject to periodical fits of depression and who at these times is inclined to excessive indulgence in stimulants. The lady is between 50 and 60 years of age, is troubled six or seven times a year, and is willing to be advised and guided to overcome her weakness. She would pay £1 15s. per week for her board, &c., as a paying guest, and the undersigned can testify that the lady is an intelligent and pleasant person.

I am, Sirs, yours faithfully,

Earl's Court-road, W., July 16th, 1900. J. ROSS MACMAHON.

SANITARY PROPAGANDA.

To the Editors of THE LANCET.

SIRS,—In many rural districts the sanitary authorities issue printed leaflets for distribution amongst cottagers. These leaflets contain instructions how to act when notification diseases appear. Can you kindly inform me where such can be obtained and which is the best form for scarlet fever and diphtheria?—I am, Sirs, yours faithfully,

July 16th, 1900. HEMERA.

*** The medical officer of health composes his own propaganda to the people under his sanitary charge. (See the paragraph entitled "Precautions against Diarrhœa.") If any medical officer of health has designed a leaflet that he thinks would be useful to our correspondent and will send it to us we will forward it to its destination and say at the same time who is its author.—ED. L.

PRECAUTIONS AGAINST DIARRHŒA.

DR. E. M. SMITH, medical officer of health of York, has issued a leaflet for distribution which contains valuable advice to the community under his charge. He is dealing with the prevention of summer diarrhœa, and the burden of his words is that cleanliness, and cleanliness alone, will prevent this disease that is so often fatal in epidemic form to children. "Keep your house clean in every part,' he says. "Keep yourselves and your children and their clothing clean. Keep your sinks, gulleys, and closets clean with brush or mop and hot water and soda. Flush them frequently with cold water. Keep the windows of your living rooms and bedrooms open by day and your bedroom windows open by night. Don't block up your bedroom chimneys and fire-places. Keep all feeding utensils constantly clean and sweet with boiling water. Don't let dust, or manure, or kitchen refuse (vegetable refuse, potato parings, tea leaves, bits of meat or fish, &c.) collect in the house or yard. Burn the kitchen refuse on the fire. Never allow choked drains, or choked closets, or offensive accumulations near your house to remain unattended to. Report them and also report badly-paved yards. Don't keep poultry in your yard. Use disinfectants such as chloride of lime freely to drains, gulleys, closets, and privies. Ask for some at the sanitary office. Don't allow your house to be damp without reporting it to the sanitary office." We trust the people of York will take this excellent advice.

"WHO IS MR. W. HARTLEY AUSTIN"?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 14th, p. 147, you are good enough to refer to a circular issued by myself to medical men on the subject of investments at compound interest and simple interest. You evidently desire to know the *bona fides* of the investment referred to, and as it is a subject which has created much interest amongst medical men (many of them investing largely) I have pleasure in replying to your queries. I do not wish to obtain a gratuitous advertisement, but I trust you will give my reply the same prominence that you have given your criticism. The company referred to as guaranteeing the investment is the Sun Life Insurance Company of Canada. The assets of this office (invested under stringent supervision of the Canadian Government) at the

present moment exceed £2,000,000 sterling. It reports annually to the Board of Trade in this country and it has appointed three trustees to look after the interests of policy-holders and investors here—viz., the Marquis of Dufferin and Ava, the Earl of Albemarle, and Sir Charles Dalrymple, Bart., M.P., who holds £100,000 in trust as special security. The company has been established since 1865 and its bankers are the Bank of Scotland. Regarding the investment itself, as stated in my circular the principal attraction is that under it any healthy man can set aside a moderate sum each year (just so much as he can afford to save against retirement later on in life, with the drop in income which retirement always entails to a medical man), accumulate same at compound interest, drawing the result either in cash or as a yearly addition to the income. You are, of course, perfectly right when you say that most medical men know that an investment at compound interest increases more rapidly than one at simple interest, but how many men realise the extraordinary difference there is between compound and simple interest. Here is an example (very far-fetched, of course, but it serves to illustrate my meaning) which appeared in one of your contemporaries a short time since. If a penny had been invested in the year 1 at 5 per cent. compound interest it would now amount to no less than 56,535,727 quintillions of pounds sterling. The same penny invested at 5 per cent. simple interest would not amount to eight shillings! I do not suggest that any medical man can set aside a penny and accumulate it for 1900 years, but I do suggest, and that most emphatically, that he cannot do better than set aside £10, £20, £50, £100 a year, or any sum he can spare, and let it accumulate for, say, 20 years under the security I have named. Should the investor unfortunately die, even a day after payment of his first deposit, all further cost immediately ceases, and the company guarantees to hand over either a large sum in cash, or to pay a yearly income to wife, child, or other dependant. Thanking you for the very fair criticism you made on my circular, and holding all further information at your disposal,

I am, Sirs, yours faithfully,
W. HARTLEY AUSTIN.

93, Queen Victoria-street, E.C., July 14th, 1900.

THE WAY TO SPREAD DISEASE.

IN spite of legal enactments, of health lectures, and the advance of general intelligence of which we are so proud, instances of ignorance or recklessness still occur. An inspector of nuisances saw a child playing in the street at Weaste on July 1st "in the peeling stage of scarlet fever." On the next day he went to the house and found the child, instead of being isolated, playing in a living room. On the 5th the child was seen again in the street. A fine of £1 and costs was imposed. The stipendiary spoke seriously to the parents, and we may presume that they were impressed thereby.

REMEDIES FOR SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—I have been appointed surgeon to a steamer of one of the Atlantic lines and whilst a good sailor myself I have no doubt I shall find many of my fellow voyagers suffering from sea-sickness. Could any of your sea-faring readers kindly tell me what remedies he has found most effectual in the treatment of this distressing complaint? Any suggestions will be esteemed a favour by

Yours faithfully,
July 13th, 1900. SHIP'S SURGEON.

"A GOOD BICYLE SADDLE."

A CORRESPONDENT, "B," asks a question in THE LANCET of July 7th, page 70, to which, in ignorance of the querist's physique, it is impossible to give a satisfactory answer. A cyclist requires to be measured for his saddle just as much as for the garments he wears when riding. What suits a man with lean thighs will be found extremely uncomfortable by the possessor of rounded limbs, and *vice versâ*. Again, there are riders who cannot bear pressure on the perineum, whereas others—with, for instance, a tendency to procidentia recti—must have support in that region. There are many so-called anatomical saddles in the market, but no particular pattern can be recommended for all and sundry. If "B" were to write to any well-known firm of saddle-makers describing his physical conformation and disabilities (if any) he would no doubt succeed in obtaining what he wants. There are so many firms turning out equally good articles that it would be invidious to make a selection. "B" can, however, find names and addresses in the advertising columns of cycling journals. With regard to position it is unquestionably true that by perching himself upon an inclined plane and bending his body forwards at an acute angle in the ungraceful manner that is adopted by the numerous class of cyclists known as "scorchers" the rider is able to exert a slightly greater amount of propelling force than he can when sitting upright, but there are happily objections to the stooping posture which more than counterbalance this advantage. In the first place persistence in the hunchbacked attitude not only conduces to the production of high shoulders, narrow chests, and rounded backs, but it also, to a great extent, deprives the devotee of speed of the ability to enjoy delightful scenery and objects of interest. His neck curved downwards and his head protruding in tortoise guise, he can see nothing but the space immediately in front of his rapidly revolving wheel. At a rate which cannot but be startling to even experienced pedestrians he silently flashes past, the embodiment of anything except the poetry of motion, and as he momentarily glances upwards the expression in his straining eyes is precisely the same as that which their misfortune has imposed upon the victims of dorsal caries. A dignified cyclist holding his head heavenwards like a man and not earthwards like a beast is a spectacle to admire; but although he may succeed in covering more miles within the hour the grovelling scorcher is nevertheless an execrable object who, for no good or useful purpose is content to sacrifice everything that is æsthetic on the altar of celerity.

RADIOGRAPHIC EQUIPMENT.

MESSRS. ISENTHAL & Co., of 85, Mortimer-street, Cavendish-square, W., have submitted to us their new list of radiographic apparatus. We note that their "x" ray laboratory is connected with both the continuous and alternating current so that the working of every instrument in the list can be shown by those who contemplate studying the subject in its practical aspects. The list contains a description of the "tubes" which according to experience are best for all practical purposes. In addition all the photographic and other accessories which make an equipment complete are given.

Senex.—The purchase value is estimated on the gross annual receipts and a three years' average would be a fair way of estimating it. The purchaser is sure to require an inspection of the books and so will be able to judge how far the last three years' work represents an increase or decrease in the practice. With the introduction that "Senex" proposes to give, it would be usual to ask for the half share a sum equivalent to the gross average annual receipts of the practice. We think our correspondent would be well advised to employ an agent.

W. H.—The notice would certainly seem to be designed to steal a march upon a professional brother. Where is the said notice "put up" and how much publicity has it received? Our correspondent will understand that if we comment on this matter the fact that we obtained our information from him may be obvious whether his name is mentioned or not.

Delta.—We cannot say whether the General Medical Council would, on a complaint being made, construe such an action as infamous in a professional respect, but thus to assist an unqualified person to practise medicine by writing the legal certificates for him is, in our opinion, covering and a very grave breach of professional manners.

Rivers.—We understand that it is the author's intention to treat the subject as a whole and it would be as well to make the illustrations generally illustrative and not to confine them to views of one sanatorium.

Jupiter will find the information he requires in THE LANCET of Sept. 9th, p. 724, and of Sept. 23rd, 1899, p. 851. The lists are no longer exhaustive.

SATURDAY (28th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfie'd: Consultation. (Skin.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Dr. Cathcart: Miscellaneous Cases. (Post graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Bidwell: The Preparation of Patients before and the Treatment after Operation.

TUESDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. E. Squire: Consultation. (Medical.)

WEDNESDAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Hillier: Consultation. (Medical.)

THURSDAY (26th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos-street, Cavendish-square, W.).—9 A.M. Educational Committee. 9.30 A.M. Parliamentary Committee. 10 A.M. Council Meeting. 11 A.M. Fifty-ninth Annual Meeting. Election of Officers and Committee. 2 P.M. Dr. F. Beach: Presidential Address.—Dr. W. W. Westcott: Inebriety, its Causes, Results, and Treatment.—Dr. E. Daunt will read a paper. 8 P.M. Annual Dinner at the Whitehall Rooms, Hôtel Métropole.

FRIDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Gunn: Consultation. (Eye.)

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos street, Cavendish-square, W.).—10 A.M. Microscopic Demonstrations, Preparations, Specimens, and Lantern Slides:—Dr. W. F. Robertson, Dr. J. S. Bolton, and Dr. G. A. Watson. Dr. H. H. Newington will exhibit and describe the Plans of the New East Sussex Asylum. Dr. D. Orr and Dr. T. P. Cowen: A Contribution to the Morbid Anatomy of General Paralysis of the Insane (microscopic and lantern demonstration).—Dr. J. O. W. Barratt: Two Cases of Lepto-meningitis (microscopic and lantern demonstration).—Dr. J. Turner: Some Alterations produced by Disease in the Giant Nerve-cells of the Cortex (microscopic and lantern demonstrations).—Dr. L. C. Bruce and Dr. H. de M. Alexander: Observations upon the various Physical Changes in the Acute and Subacute Stages of Melancholia. 2 P.M. Mr. C. F. Beadles: The Insane Jew.—Dr. W. C. Sullivan: Alcoholic Homicide.—Dr. D. Blair: Non-diabetic Glycosuria.—Dr. A. F. Shoyer: An Angeioma of Broca's Convolution in a Lunatic.—Dr. F. W. Edridge-Green: Psycho-physical Perception.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

BRITISH MEDICAL ASSOCIATION MEETING AT IPSWICH.

DURING the forthcoming meeting of the British Medical Association at Ipswich the representatives of THE LANCET can be consulted at the Great White Horse Hotel, Ipswich, with regard to our reports of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Derbyshire Courier, Newcastle Daily Chronicle, Manchester Guardian, East Anglian Daily Times, Blackburn Telegraph, Gainsborough Leader, Staffordshire Sentinel, Norfolk Weekly Standard, Dover Standard, Midland Free Press, Liverpool Daily Post, Middlesborough Morning Mail, Daily Mail, South Wales News, Bristol Mercury, Bradford Observer, Market Harborough Mail, West Morning News, Yorkshire Post, Citizen, Scotsman, Builder, Times of India, Arbroath Herald, Daily Express, Architect, Leeds Mercury, Local Government Chronicle, Hertfordshire Mercury, Daily Express (Dublin), Mining Journal, Surrey Advertiser, Irish Times, Kentish Mercury, Liverpool Journal of Commerce, Local Government Journal, City Press, Reading Mercury, Ripley Advertiser, Warwick Times, Evesham Standard, Clapham Observer, Thirsk News, Stafford Advertiser, Wigan Observer, Woolwich Herald, Wiltshire Telegraph, Grimsby News, Cheshire Observer, Gloucester Standard, Pioneer Mail, Ilkeston Advertiser, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Mr. A. Anderson Sunderland; Messrs. Arnold and Sons, Lond.; Messrs. Allen and Hanburys, Lond; Aston Hall, Sutton Coldfield, Secretary of; A. D. H. Mons, Alcan, Paris; *Australian Trading World*, Editor of.

A Clinical Lecture

ON

PANCREATITIS, WITH ESPECIAL REFERENCE TO CHRONIC PANCREATITIS,

ITS SIMULATION OF CANCER OF THE PANCREAS AND ITS TREATMENT BY OPERATION, WITH ILLUSTRATIVE CASES.

Delivered at the Medical Graduates' College and Polyclinic on July 18th, 1900,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY; AND HONORARY PRESIDENT OF THE SURGICAL SECTION OF THE THIRTEENTH INTERNATIONAL MEDICAL CONGRESS.

GENTLEMEN,—To be asked to lecture before an audience of post-graduates must always be considered an honour, but when the request comes from such a distinguished body as the council of the Medical Graduates' College and Polyclinic one can only feel that to the honour is added the pleasure of compliance. Fortunately, too, I had a subject which I wanted an opportunity of bringing forward, and I hope that I may have the benefit of your criticisms and the advantage of help from your experience in a class of cases which has hitherto, scarcely, if at all, been generally recognised, but which I believe to be not very uncommon.

Before proceeding to consider the subject of chronic pancreatitis specially I think that it will tend to the elucidation of my subject if I make a few remarks on pancreatitis generally.

PANCREATITIS.

When it is borne in mind that the pancreas is a racemose gland with its various channels opening into a duct which opens along with the common bile-duct into the second part of the duodenum—a channel usually containing septic organisms, and frequently liable to catarrh and other disorders—it is not surprising that inflammation should frequently occur in it. Just as in the liver we may have acute and chronic catarrh of the ducts, infective and suppurative cholangitis, and inflammation of the inter-lobular tissue ending in cirrhosis, so in inflammation of the pancreas we may have any one or more of those affections, though as yet we have not learnt to recognise acute or chronic catarrh of the pancreatic ducts apart from jaundice, or infective and suppurative inflammation of the ducts apart from abscess of the pancreas itself. As our means of diagnosis become more perfect I venture to predict that these affections will be more frequently recognised and awarded their proper place in medicine.

I have seen cases of discomfort with some swelling at the epigastrium associated with dyspepsia and ague-like attacks but without jaundice, or with only very slight jaundice, which I thought might be explained on the hypothesis of infective inflammation of the pancreatic duct, the cases having cleared up under general treatment. I have also seen the same symptoms associated with more pain, irregular fever, more marked swelling and tenderness over the pancreas and discharge of pus by the bowel from time to time, but without any collection sufficiently large to form a distinct abscess. In a case of this kind seen lately the question of operation was raised, but in the absence of distinct abscess of the pancreas it was not pressed and the patient is recovering. I think that this may have been an affection of the pancreas analogous to suppurative cholangitis.

Causes.—The essential and immediate cause of the various forms of pancreatitis is bacterial infection, this having been positively proved in a number of cases both clinically in the human subject and experimentally in the lower animals, but as in inflammatory affections of the liver and bile-ducts we look for extrinsic causes, so in pancreatic diseases we find biliary and pancreatic lithiasis, injury, gastro-duodenal catarrh, ulcer and cancer of the stomach, pylorus, or duodenum, and zymotic diseases such as typhoid fever and influenza, to be determining factors, though in some cases pancreatitis has come on suddenly in persons in robust health and the determining cause has been beyond recognition. Though the infection may arise from the blood as in pyæmia, or by direct extension from the neighbouring tissues as in ulcer of the stomach, yet the most usual channel is through the duct, as in the cases related below arising from gall-stones in the common duct, and from gastro-duodenal catarrh.

Symptoms.—It seems to me more convenient to consider pancreatitis clinically under the headings of (1) acute, (2) sub-acute, and (3) chronic, which does not interfere with the pathological classification of acute pancreatitis into hæmorrhagic, suppurative, and gangrenous. The symptoms of pancreatitis are very variable and differ in the separate forms. It is a disease without pathognomonic signs and a correct diagnosis is usually only arrived at by a careful study of the history, mode of onset, and combination of symptoms.

1.—ACUTE PANCREATITIS.

This is usually ushered in by a sudden pain in the superior abdominal region, accompanied with faintness or collapse and followed sooner or later by vomiting. It is almost constantly accompanied by constipation, so that it is quite usual for these cases to be mistaken for intestinal obstruction at first. The obstruction, however, is not absolute, flatus passes, and a large enema may secure an evacuation; if the patient survive for several days diarrhœa may supervene. The pain may be so severe as to produce syncope or collapse, and though the pain does not quite pass away it has a tendency to be paroxysmal and to be increased by movement; it is associated with well-marked tenderness just above the umbilicus or between it and the ensiform cartilage. The pain is soon followed by distension in the superior abdominal region which may become general and usually does so in the later stages, and by vomiting, first of food then of bile. The vomiting may be severe and each seizure may aggravate the pain, but at times vomiting may not be a prominent symptom. Slight icterus from associated catarrh of the bile-ducts is usually present and deepens the longer the patient survives. The aspect is anxious and the face is pinched, resembling the facies of peritonitis, which in fact may be present. The pulse, which is rapid and small, is a better guide than the temperature, which may be normal, subnormal, irregular, or high. Delirium comes on in the later stages. The distension, pain, and tenderness prevent an exact examination of the pancreas, which would otherwise be found enlarged. Death usually supervenes from the second to the fifth day from collapse, though in the less acute cases life may be more prolonged. Acute infective pancreatitis thus takes on the form of acute peritonitis starting in the superior abdominal region. If life be prolonged the case comes under the category of sub-acute pancreatitis, and in that case the onset is usually less grave, though often equally sudden.

2.—SUB-ACUTE PANCREATITIS.

This may have a sudden onset with acute pain and vomiting associated with constipation, but the collapse is not so marked and may even be absent; the upper abdominal region does not become so rapidly swollen, and vomiting is less severe and less prolonged. At other times the onset is more gradual, though the symptoms may be similar. Tenderness over the pancreas is well marked and on account of the tympanites being less than in the acute form it may be possible to feel the swollen gland, especially under an anæsthetic. Constipation gives place to diarrhœa, and pus or blood may be noticed in the stools which have a very fœtid odour. The pulse will be less rapid and less thready than in the acute form, and the temperature is more irregular. I have seen the temperature reaching 104° and 105°F., and yet the pulse to vary between 90 and 110. The morning temperature may be normal and the evening temperature high for several days or even weeks. Rigors may occur and may be repeated from time to time. The pain occurs in paroxysms, but there is also a constant dull pain at the epigastrium. The patient may lose the more urgent symptoms and appear to be really improving, but the loss of flesh and feebleness continue and relapses usually occur, leaving the patient each time more and more feeble until death supervenes from asthenia. Albuminuria is pretty constant, but glycosuria is rarely present and lipuria is an uncommon symptom.

If an abscess develop the pus may form a tumour projecting in the superior abdominal region and forming a tender swelling behind the stomach, or perhaps coming to

the surface above or below that viscus; or it may burrow into either loin forming a perirenal abscess, or passing under the diaphragm, it may form a subphrenic abscess. Occasionally the pus may follow the psoas muscle and form a subperitoneal abscess in the iliac region or even passing over the brim of the pelvis it may collect in the left broad ligament. I have seen these several terminations in cases either under my own care or under the care of colleagues and I have operated four times for abscess of the pancreas. Sometimes the abscess bursts into the stomach and is vomited, or into the bowel and is voided per anum, after which diarrhœa may continue and pus may be seen from time to time as any fresh collection forms and bursts. I have seen both of these methods of evacuation of the pus. With the evacuation of the abscess relief occurs for a time and the temperature improves, but relapses usually occur and a mild form of septicæmia persists with a hectic temperature. Death is the usual termination, but recovery may occur after a tedious and prolonged illness, as in the case now related.

CASE 1.—On March 17th, 1900, I was asked by Dr. J. Glen of Middlesbrough, to see a female patient, aged 26 years, when I obtained the following history. The patient was first attended the last week of December, 1899. Her symptoms then indicated a chronic form of dyspepsia with recurrent attacks of diarrhœa, the latter associated with indurated fæces. No relief from treatment resulted. The main symptoms at this time were general tympanitic condition of abdomen with tenderness over the sigmoid flexure, no acceleration of pulse, and no rise of temperature. About the second week in January, 1900, the diarrhœa still persisting, a good deal of fresh blood was present with each evacuation—these giving one the idea of dysentery. Then retching and vomiting set in, but this condition was probably set up by the free exhibition of powder of ipecacuanha. This condition continued more or less for upwards of a fortnight when improvement set in. The tympanites disappeared, the tenderness of the left groin became less, there was less sickness, and a desire for food returned. The diarrhœa abated, there being only one or two evacuations in the 24 hours, the motions being formed. The improvement continued till the second week in February. The patient at this time having gained flesh, was daily gaining strength, and was able to sit up in her dressing-gown for a time each day. A relapse took place, accompanied with much pain in the epigastric region, constant sickness, return of diarrhœa and blood in the stools, and rapid emaciation, and quick pulse and rise of temperature. This condition persisted in spite of all treatment. There had never been blood in the vomited matter except once, when there was a slight streak as if it might have come from the pharynx during the act of severe retching. Since the relapse there has developed a dull area with tenderness over the pancreas, but the degree of tenderness varies from day to day. At one time there was retention of urine, afterwards incontinence; no albumin or sugar was present. Hæmorrhage was very profuse, the blood being gruel-like and mixed with stools which were very offensive. Dr. Glen showed me the report of the Clinical Research Association of an examination of the fæces which contained some blood and pus but no cells suggestive of growth and no tubercle bacilli. When I saw her the patient was looking very ill and emaciated, with feeble, quick pulse; there was tenderness in the superior abdominal region with rigid recti, but not along the course of the colon either on the right or the left side. Examination under an anæsthetic revealed a swelling in the situation of the pancreas, but no fluctuation could be made out. As there was resonance in front of it, it was clearly behind the stomach, and from its position it was above the colon. Before the anæsthetic the patient said there was very great tenderness on pressure over the swelling in the epigastrium. The rectal examination was negative, except that there was ballooning. I made a diagnosis of suppurative pancreatitis, the abscess having discharged into the bowel. I advised five grains of salol, two grains of quinine, and half a grain of opium, to be given thrice daily, the patient to be watched with a view to the testing of her temperature, pulse, &c. Plasmon and somatose dissolved in broth, tea, &c., were ordered as the patient could not take milk. The question of operation was raised and dismissed to be further considered in about a week or 10 days, as she was at the time too feeble to bear even an exploratory incision. From this time improvement steadily occurred and when I saw her again in a fortnight she was picking up distinctly, though there was still well-marked tenderness over the pancreas. In June she had gained nearly a stone and a half in weight, looked much better, and could take her food well; there was however, still a little rigidity of the recti and some tenderness, though no distinct tumour of the pancreas. The diarrhœa had disappeared and there was neither pus nor blood in the motions.

3.—CHRONIC PANCREATITIS.

Chronic pancreatitis, at first hypertrophic but later cirrhotic, is usually considered to be a very rare disease, but experience would lead me to believe it to be a much more common affection than the acute or sub-acute forms, and I think that some cases put down as malignant disease of the head of the pancreas and terminating fatally may be cases of chronic interstitial pancreatitis. My reason for this belief is shown in the cases related below, selected out of 17 cases on which I have operated. My experience has resulted from my having operated on a large number of cases of jaundice depending on obstruction to the common bile-duct; the obstructive jaundice, wasting, paroxysmal attacks of pain and ague-like seizures having given rise to the suspicion of gall-stones, and the absence of relief by medical treatment having rendered surgical treatment necessary. My first case of this nature was a revelation to me, as the patient was extremely ill before the operation which was, in fact, undertaken too late; and as there was the opportunity of a post-mortem examination the absence of malignant disease or of other cause than the chronic pancreatitis and associated jaundice to account for the death was directly proved.

This form of pancreatitis is quite distinct from the acute or sub-acute form, though I think it is probable that some of the latter cases end in chronic interstitial pancreatitis. It probably usually arises by extension of the inflammation from a chronic catarrh of the pancreatic duct extending from a gastro-duodenal catarrh, though it is frequently associated with biliary or pancreatic lithiasis, or with gastric, pyloric, or duodenal ulcer. Its course varies. The onset may be quite gradual and painless, or may be ushered in by a severe pain at the epigastrium followed by jaundice resembling a gall-stone attack and associated with nausea and vomiting, and perhaps followed by a feeling of chilliness or even a rigor. The pain, however, is not over the gall-bladder and does not pass round the right side to the subscapular region, but is central and passes backwards to the midscapular region or round the left side, thus resembling stomach rather than gall-bladder pain. The tender spot is usually an inch above the umbilicus in the middle line and not over the gall-bladder as in cholelithiasis. When once jaundice has come on it tends to deepen with each attack until it becomes continuous and chronic. The paroxysms of pain may be repeated more or less frequently or there may be no paroxysmal pain, merely a dull ache deeply seated, burning and boring in character. A swelling of the pancreas may sometimes be made out, but as the recti are rigid because of the pain and tenderness in the epigastrium, it can usually only be discovered under anæsthesia.

Loss of flesh and strength are well-marked symptoms in all cases. Vomiting may in some cases be absent, but there are usually a want of appetite and flatulent dyspepsia, and always a sense of fulness and weight at the epigastrium for some time after food. Jaundice is not necessarily present at first, though it is usually present at some stage of the disease and is often well marked, but, as was pointed out some years ago by Dr. Walker of Peterborough, the stools are white even when the pancreatic fluid alone is absent from the intestine. Diarrhœa is often present and the stools are offensive and may be fatty. Albuminuria is common and glycosuria may occur, but the latter is probably only present in cases where the whole gland is affected. Fever may be absent, but in some cases the temperature runs a hectic course, always rising in the evening and falling in the morning. This is especially the case where ague-like paroxysms occur. These varieties probably depend on the character of the infection in the pancreatic and bile-ducts and also on the amount of obstruction present. Where jaundice is present the pulse may be abnormally slow, and even when the temperature is raised the pulse-rate is not much elevated, though the character of the pulse may be poor. In the later stages, especially if the disease be associated with jaundice, hæmorrhages from the nose and the bowel, vomiting of blood and petechiæ in the skin show marked blood degeneration and death ensues from increasing weakness.

In the more chronic cases, especially when there is contraction of the head of the pancreas, there will be found a tumour formed by the distended gall-bladder, just as there is in cancer of the head of the pancreas, for which disease chronic interstitial pancreatitis is then apt to be mistaken and a hopeless prognosis given. In such cases the gall-bladder will be found to be distended with mucus, the bile which first filled it having become gradually absorbed, the backward pressure having prevented fresh bile from entering the ducts. This may occur so gradually as to be painless and then the gall-bladder is free from tenderness, which is seldom the case when the distension is due to gall-stones.

Diagnosis.—The diagnosis of chronic interstitial pancreatitis has to be made from gall-stones in the common duct, cancer of the head of the pancreas, cancer of the liver and bile-ducts, and chronic catarrh of the bile-ducts. From gall-stones the diagnosis is of no great importance, since the two diseases are often associated and the treatment is the same; nevertheless, it may be possible to make a diagnosis of gall-stones by the sequence of long antecedent history of spasms without jaundice, then by a severe attack of pain followed by jaundice, and after a time by recurring pains with increase of the icterus associated with ague-like attacks. The absence of tumour is more common in gall-stones than in chronic pancreatitis, though in the latter the gall-bladder may be found contracted at times. Although in pancreatitis there is usually less pain, at times the paroxysmal attacks may be equally as severe as in gall-stone seizures. The tenderness in the latter case, however, will be over the gall-bladder, and in the former at the middle line where the swollen gland can sometimes be felt, especially if the examination is made under anæsthesia; moreover, the radiating pain in gall-stones is towards the right and in pancreatitis towards the left or to the mid-scapular region. In cancer of the head of the pancreas the onset is usually gradual and painless, and the disease generally occurs later in life, usually after 40 years of age. It is preceded by general failure of health, and when the jaundice supervenes it becomes absolute and unvarying and is nearly always associated with a tumour of the gall-bladder, which generally attains a large size and shows no tenderness on manipulation. The liver enlarges from the biliary stasis, but there are no nodules to be felt. In some cases of cancer of the head of the pancreas a hard nodular tumour may be found on the inner side of the distended gall-bladder. Extremely rapid loss of weight and strength with increasing anæmia, but without ague-like seizures, is very characteristic, and it is common for there to be an absence of fever with a slow feeble pulse and later ascites with œdema of the lower limbs. Cancer of the common bile-duct is rare, but when present may resemble, and is usually associated with, gall-stones. In cancer of the liver, the irregular enlargement, the nodular feel, the rapid deterioration of health, the less intense jaundice, and the absence of fever and paroxysmal pains will usually enable a diagnosis to be made. Chronic catarrh of the bile-ducts is usually associated with an absence of symptoms, except jaundice and some loss of flesh. The entire absence of pain and fever with the relief by treatment usually give rise to little difficulty in establishing a diagnosis. In many cases a diagnosis will only be made by an exploratory operation, then the enlargement of the pancreas can be readily felt, or if the tumour be small the head of the pancreas may be found to be hard and perhaps nodular like scirrhus. If ascites be present the tumour will probably be malignant. The lymphatic glands in the lesser omentum may be enlarged in both cancer and chronic pancreatitis, but in the latter they will be discrete and soft, in the former hard and perhaps infiltrating. Adhesions are usually associated with chronic pancreatitis, but are generally absent in cancer.

Pathological appearances.—Whenever there is obstruction of the common bile-duct by gall-stones, with associated infective cholangitis, the pancreatic duct may be subjected to backward pressure and to the same infective dangers as the liver; hence the association of infective and suppurative inflammation of the pancreatic duct is quite common. If this irritative process is kept up for some time the substance of the pancreas participates in the inflammatory process and an interstitial pancreatitis results. There may be uniform swelling of the gland or only of certain lobules. Effusion into the inter-lobular and into the peri-glandular cellular tissues is associated with proliferation and detachment of the epithelium lining the acini and the tubes, and there is a crowding together of the cells, with an accumulation of inflammatory fluid containing round cells and blood corpuscles in and around the affected parts of the gland, leading to tension. This simple pancreatitis is known by examining the parts of the pancreas less severely affected when death has occurred from abscess or other disease affecting a limited portion of the gland, and I have also seen it in cases of common bile-duct obstruction where the pancreatitis only proved a secondary and not the fatal disease. In the greater number, if not in all cases of obstruction of the common duct where the obstruction is close to the duodenum the pancreatic duct participates in the infective process which usually follows, and when death occurs it will be found that pus can usually be squeezed from the duct of Wirsung; this has been observed independently by Dr. A. R. Ferguson of Glasgow. If resolution takes place complete recovery may occur or the interstitial effusion may organise and lead to irregular contraction of the tissues and possibly to cirrhosis or chronic interstitial pancreatitis that may either end in diabetes if the whole gland be affected or may lead to pressure on, or distortion of, the common bile-duct and so to chronic jaundice, thus simulating cancer of the head of the pancreas. If, on the other hand, the inflammation be too acute for resolution to occur it may pass on to suppuration which may be general or localised. In all cases of chronic pancreatitis on which I have operated I have found numerous and firm adhesions around the duodenum, pylorus, and hepatic flexure of the colon, all of which have been adherent to the liver and gall-bladder, and on several occasions occlusion of the foramen of Winslow has been found. Where there has not been associated cholelithiasis, the gall-bladder will usually be found distended, and if the obstruction of the common duct be complete it may be very large and filled with mucus. The lymphatic glands usually participate in the inflammatory process and may suppurate. If the patient survive there may be abscesses in the liver, pressure on, or thrombosis of, the splenic vein, enlargement of the spleen, pressure on, or thrombosis of, the portal vein with ascites, or even obstruction to the flow of blood through the vena cava and œdema of the legs.

Prognosis.—The disease may last for months or even years, and it is not improbable that some of the cases of jaundice persisting for several years and called chronic catarrh of the bile-ducts may be of this nature. If glycosuria supervene it makes the outlook more grave. Increasing weakness and the supervention of hæmorrhagic tendencies usually show the near approach of a fatal termination. Under surgical treatment the prognosis is very favourable, as out of 17 cases on which I have operated 16 have recovered, and in nearly every case complete restoration of health has occurred.

TREATMENT OF PANCREATITIS.

In acute infective pancreatitis treatment practically resolves itself into that of peritonitis commencing in the superior abdominal region. The pain at the outset is so acute as to necessitate the administration of morphia, and the collapse will probably demand stimulants, which on account of the associated vomiting may have to be given by enema. In the early stages the symptoms are so indefinite that the indications for surgical treatment are not clear enough to warrant operation, and until the collapse has passed off no surgical procedure would be justifiable. The simulation of intestinal obstruction will probably lead to efforts to secure an evacuation of the bowels and relief to the distension. In the only case of this kind that I have seen the distension of the upper part of the abdomen was so great and the patient was so obese that any exploration from the front was out of the question, even when the diagnosis was established. A posterior exploration was discussed and would have been made but for the speedy death of the patient. Just as in a perforative or gangrenous appendicitis an early evacuation of the septic matter is necessary to recovery, so in this equally lethal affection an early exploration in the left costo-vertebral angle is demanded, and as it can be performed with very little difficulty I should certainly perform it early in any case I might see in the future, when I should evacuate the septic material and adopt free drainage.

The sub-acute form of pancreatitis is much more amenable to treatment, as the indications are so much more definite and there is more time for careful consideration, and though it has usually only been attacked when an abscess has formed and is manifestly making its way to the surface, yet there is no reason why in some cases surgical treatment should not be adopted at an earlier stage. As in the acute condition, morphia may be required to relieve the

paroxysmal pain and stimulants and food by the rectum to relieve the collapse and support the strength. The distension, if present, may also demand attention and may have to be relieved by lavage of the stomach and turpentine enemata or by the administration of calomel by the mouth. Calomel is also of benefit by acting as an intestinal antiseptic, for which purpose it may be given in small repeated doses or in doses of five grains, followed by a saline aperient. As soon as the constipation is relieved diarrhœa is apt to supervene, when salol and bismuth with small doses of opium may be given. If surgical treatment is decided on, a median incision above the umbilicus will enable the operator to palpate the pancreas and locate any incipient collection of pus, which if practicable should be evacuated by a posterior incision in the left or right costo-vertebral angle, or failing that possibility the collection of pus may be aspirated and the cavity opened and packed with gauze, which may be brought forward through a large rubber drainage-tube which will in the course of from 24 to 48 hours establish a track isolated from the general peritoneal cavity. In one case I was able to do this, but the operation was undertaken at too late a stage to be successful, and though the patient lived two or three days afterwards the evacuation of the pus seemed to make very little difference to the general septic condition previously existing and death occurred from increasing debility. The method adopted had, however, been successful from the point of view of drainage, and the track of the gauze and tube was isolated from the general peritoneal cavity. If a definite abscess form and approach the surface in front or in either loin the treatment will be that of incision and drainage as in the case of any other abdominal abscess. Of four cases on which I have operated two recovered completely, one recovered from the operation but died a few weeks later from debility. The fourth case is the one just referred to. The strength must be maintained by careful feeding and the judicious administration of stimulants. It will be necessary to keep a sharp look-out for further collections of pus and for subphrenic abscess or empyema which on recognition will need treatment.

The course and treatment of chronic interstitial pancreatitis is exemplified in the cases related below. Doubtless, in some of these cases the manipulation of the indurated tumour has detached calculi impacted in the gut, but in others the relief of tension as the result of draining the bile-ducts by cholecystotomy or cholecyst-enterostomy has indirectly drained the pancreatic duct and thus has led to a subsidence of the pancreatitis, then to an opening of the common duct by the relief of the tension, and so to a cure of the patient. The simulation of malignant disease of the head of the pancreas by chronic interstitial pancreatitis would make me hesitate to decline operation in any case of distended gall-bladder where the patient was in a condition to bear it, or even in any case of chronic jaundice without distension of the gall-bladder where the general health was deteriorating, as though it should be recognised that if the disease be really malignant very little good will be done and life may even be shortened or prolonged for a short time, yet if the disease prove to be chronic pancreatitis a real and permanent cure may be brought about. If a calculus be felt imbedded in the head of the pancreas or impacted in the pancreatic duct it may be reached through the second part of the duodenum by laying open the papilla and exploring the duct or by dividing the peritoneum passing between the duodenum and hepatic flexure of the colon and then cutting through the overlying pancreas on the concretion. If the papilla be incised it does not require suture and in the cases in which I have explored the ducts by the duodenal route there has been no hæmorrhage; the anterior duodenal opening requires closing by a mucous and a serous suture. Drainage of the right kidney pouch for from 24 hours to 48 hours is advisable, though not always necessary, and this is best done by a stab wound at the most dependent part.

For attacking the head of the pancreas or the pancreatic duct a vertical incision should be made through the right rectus and not in the middle line. In all cases of deep jaundice I prescribe chloride of calcium in 20-grain doses thrice daily for 24 hours or 48 hours before operation and give it in an enema form for 24 hours afterwards in 60-grain doses thrice daily.

CASE 2. *Chronic pancreatitis; cholecystotomy; cure.*—A man, aged 45 years, was sent to me on Oct. 25th, 1898, by Dr. J. B. Berry of Keighley. The patient was very deeply jaundiced and told me that he had lost a stone in weight since the onset of his illness five weeks before. He gave the history of having had attacks of pain referred to the region of the gall-bladder nine years previously, but they were unaccompanied by jaundice and passed off after prolonged treatment. From that time onward he had been free from attacks of pain up to the onset of the present illness five weeks before, when he was suddenly seized with severe pain at the pit of the stomach and became jaundiced. The pain had recurred daily and had been so severe as to necessitate his taking morphia. Dr. Berry noticed a swelling in the region of the gall-bladder a fortnight after the onset of his illness, and there was all along well-marked tenderness at the epigastrium with gradually increasing enlargement of the liver. The patient's general health rapidly failed and the loss of flesh was well marked. When I saw him he looked pinched and ill, he was very deeply jaundiced, and the urine was loaded with lithates but contained neither albumin nor sugar. There were well-marked tenderness at the epigastrium and a smooth tumour, which was not very tender, in the gall-bladder region; the liver was enlarged and the edge was smooth and could easily be felt an inch below the costal margin. A diagnosis of gall-stones in the common duct was made, and the patient was admitted into the Leeds General Infirmary. The operation was performed on Sept. 27th, 1898. On opening the abdomen numerous adhesions between the gall-bladder and liver and the pylorus, colon, omentum, and duodenum were found. The gall-bladder was slightly distended, but no gall-stones were felt either in it or in the cystic or common duct. There was, however, a hard nodular swelling of the head of the pancreas which at the time was thought to be malignant. In order to give relief the adhesions were detached and the gall-bladder was drained by cholecystotomy. On Oct. 28th I wrote to Dr. Berry telling him that I feared that the disease of the pancreas might be malignant but that there was a possibility of its being a chronic pancreatitis. On Nov. 5th I wrote a letter to this effect: "I am pleased to be able to tell you that your patient has improved very much and the jaundice has nearly disappeared. I hope, therefore, that the tumour of the head of the pancreas may have been inflammatory and not malignant. At the time of operation it occurred to me that it was not quite hard enough for a malignant tumour, but under the circumstances I felt it my duty to give you my suspicions." From that time onwards recovery was uninterrupted and the patient left the hospital with the wound closed within the month. In December, 1899, the patient, at the kind suggestion of Dr. Berry, called to report himself to me. He looked perfectly healthy and had gained over a stone in weight since his return home. He had neither pain nor tenderness and he said that he felt as well as if he had never ailed anything. The scar was firm, the liver was normal, and there was not the slightest tenderness in the epigastrium or in the gall-bladder region.

CASE 3. *Chronic pancreatitis; cholecystotomy; cure.*—The patient was a man, aged 45 years, residing at Pickering. On March 19th, 1898, he was brought to see me by Mr. G. V. Robertson of Pickering, the history being that he had been well up to 12 months before, when he began to have painful attacks at the pit of the stomach ending in vomiting, but not followed by jaundice until an attack on Jan. 1st, 1898, since which time he had been deeply and continuously jaundiced. He had also from that time onwards had ague-like attacks, and two days before seeing me he had had within 24 hours three of these seizures, each accompanied by pain. Within a twelvemonth he had lost 2 st. 8 lb. in weight. On examining him there was some swelling in the gall-bladder region but no tenderness. The liver was a little enlarged but the margins felt smooth. There was decided tenderness in the middle line just above the umbilicus and on deep pressure the pain was considerable and an indefinite fulness could be felt. The diagnosis of gall-stones in the common duct was made, and an operation was advised. The patient was operated on at a surgical home on March 30th when the gall-bladder was found to be slightly distended and surrounded by adhesions to the pylorus, duodenum, colon, and omentum. No gall-stones could be discovered, but there was a well-marked swelling of the head and the first two inches of the pancreas which though nodular and irregular was not very hard. This extended further to the right than normal so as to cover in the lower end of the common bile-duct. Cholecystotomy was performed. Within 24 hours of the

operation nearly four pints of very offensive bile were discharged through the tube. A specimen was examined by the Clinical Research Association and their report was as follows: "The bile contains both staphylococci and streptococci, but no bacillus coli communis could be found either under the microscope or in the culture." Fearing that the disease might be malignant and the patient being so extremely weak and ill I gave a poor prognosis, but in a few days I was able to write: "[The patient] is progressing very satisfactorily, though he is still profoundly weak. Bile has appeared in the motions so that the obstruction is evidently overcome. The bowels have been moved naturally and the patient is less deeply jaundiced and looking better generally." On April 5th I was able to report that he was taking food well and that bile was passing freely in the motions He had had no recurrence of the shivering attacks. The drainage was continued for 14 days. On the 20th the patient returned home The urine was then free from bile and the motions were assuming a natural colour; he was taking food well, gaining flesh, and looking better generally. I still, however, gave a guarded prognosis, though I said that I hoped that the tumour would prove to be inflammatory and not malignant. From that time onward his progress to recovery was extremely rapid. A report I had of his condition from Mr. Robertson a few months later said that he was perfectly well in every respect and that he had fully regained his lost weight. I heard of this patient two years after his operation and he was still in perfectly good health.

CASE 4. *Chronic pancreatitis associated with gall-stones; cholecystotomy; cure.*—On Oct. 20th, 1899, I was asked by Dr. T. C. Squance of Sunderland to see a female patient, aged 51 years, who had been suffering for three years from attacks resembling those of gall-stones, each attack being followed by jaundice. During the past 14 weeks the seizures had been more frequent and severe and jaundice had never quite cleared away before another attack came. She had lost flesh and strength considerably and had vomited from time to time between the attacks. Her digestion was much impaired and there was a want of appetite. She had had no rigors, and had only slight fever at the time of each seizure. The urine contained abundant lithates and a slight trace of albumin, but no sugar. On examination the abdomen showed no manifest enlargement of the liver or gall-bladder, but some tenderness over the gall-bladder and at the epigastrium where there was an indefinite sense of fulness. An operation was performed on the 23rd, when after detaching numerous adhesions 15 gall-stones were removed from the cystic and common ducts, but as a large nodular mass was occupying the head of the pancreas and partly obstructing the common duct it was deemed advisable to perform cholecyst-enterostomy so as to make a permanent opening between the fundus of the gall-bladder and the duodenum. The tumour gave the impression both to myself, to Dr. F. Macrae, and to Dr. Squance that it was malignant. Recovery was, however, uninterrupted, the button was passed on the tenth day, the wound healed by first intention, and the patient immediately began to put on flesh. She returned home within the month and has since been perfectly well in every respect. It is now nine months since the operation, and her health, I am informed, is perfect.

CASE 5. *Chronic pancreatitis; cholecystendysis; cure.*—The notes of the following case have been kindly furnished by my friend Mr. Peter MacGregor of Huddersfield. The patient was a female, aged 51 years, married, and the mother of several healthy children. "Her previous history was unimportant, but for two or three years she had been a dyspeptic and during the past nine months she had been more or less continuously under medical treatment for dyspepsia and recurring attacks of 'cramp in the stomach.' ..... I first saw her on August 19th, 1899, when I got the above history, and a careful physical examination elicited nothing beyond tenderness in the pyloric region. On the 28th, I was telegraphed for to see her and found her suffering from a severe attack of gall-stone colic. She was seen at intervals from August 28th to Oct. 16th. On the latter date I found her emaciated and in more or less constant pain, with frequent attacks of colic and distress after every particle of food and with much straining and vomiting. Every variety of food had been tried, predigested and otherwise, but all with the same result—constant pain and frequent vomiting. Dr. Williams told me that he could feel a tumour in the pyloric region, but the patient was so very ill and examination caused so much distress I did not satisfy myself of the fact. No jaundice on this date, but previous attacks of colic had been followed by jaundice. On Nov. 25th the patient came into a nursing home for operation. She was then in constant pain with frequent retching, deeply jaundiced, and a perfect skeleton. Operation (Nov. 28th).—On examining the patient under chloroform a hard, rounded, irregular tumour was found between the umbilicus and the ribs. On opening the abdomen the stomach, much dilated, was found extensively adherent to the under surface of the liver and on stripping it off, a healthy gall-bladder in the normal position came into view. The right kidney, which had been diagnosed as 'floating,' was examined and the diagnosis verified, but the rounded, hard, irregular mass behind the duodenum appeared to be so undoubtedly a malignant tumour of the pancreas that the abdomen was closed and the friends were informed that the case was malignant and hopeless. After history: The temperature never went above normal; stitches were removed on the ninth day. On the fifth day after operation patient had a chop for dinner. Within a fortnight the jaundice had gone, the appetite rapidly improved, and she went home at the end of three weeks feeling much better, although the four medical men who were present at the operation all felt, and said, she would die within six weeks. On March 15th, 1900, she was plump and fat, ate anything, had had neither pain, retching, nor vomiting since the operation. Her tumour had quite disappeared and her medical man had discharged her as cured many weeks since."

CASE 6. *Chronic pancreatitis; cholecystotomy; cure.*—A woman, aged 35 years, was admitted to the Leeds General Infirmary under the care of Dr. A. G. Barrs on Sept. 11th, 1899, and transferred to me a few days later with the history of having been subject to attacks of spasm in the upper abdominal region for 12 years, the intervals between the seizures having varied from a few days to several months, but of late they had become much more frequent, and during the week before admission she had had four attacks, all severe ones. The seizures began with pain in the epigastrium accompanied by cold sweats and faintness; the pain passed through the mid-scapular and to the right subscapular region, and lasted from two to six hours, having to be relieved at times by morphia. Jaundice followed the seizures, and if the attacks recurred frequently it was intensified with each, but if there was a long interval only an icteric tinge remained. Palpation revealed a point of tenderness in the mid-line one and a half inches above the umbilicus where there was a sense of resistance with an abnormal fulness, but there was no tenderness over the gall-bladder nor could any swelling of the gall-bladder or liver be discovered. On Sept. 21st a vertical incision through the right rectus exposed adherent viscera and on the separation of the adhesions a thickened gall-bladder was exposed, but there were no gall-stones in it or in the ducts. The lower part of the common duct was surrounded and overlaid by a well-marked swelling of the pancreas which was harder than usual, but not sufficiently hard to be mistaken for cancer though it was somewhat nodular. Cholecystotomy was performed and drainage was carried out for a fortnight. Recovery was uninterrupted and the patient returned home within the month and she has remained well since.

CASE 7. *Chronic pancreatitis with gall-stone in the common bile-duct; cholecyst-enterostomy; relief; relapse.*—A man, aged 45 years, from Queensbury, was admitted into the Leeds General Infirmary under my care on Nov. 3rd, 1899, suffering from jaundice with repeated attacks of pain and ague-like seizures. He had been well up to 13 months before his admission when the attacks began and since their onset he had lost 6 st. in weight. Jaundice followed the first seizure and persisted, but after each attack of pain it was more intense. He was so weak and ill that it was feared he could not bear an operation. An enlargement of the right lobe of the liver could be felt and on its inner side in the mid-line just above the umbilicus there was another tumour situated behind the stomach. On Nov. 9th an operation was performed on a heated table with the patient enveloped in wool, an injection of 10 minims of solution of strychnia having been previously given. On opening the abdomen an enlargement of the right lobe of the liver was seen, the gall-bladder was found shrunken under adhesions, a floating gall-stone too hard to crush was felt in the common duct, and a hard nodular tumour of the head of the pancreas was discovered. As the latter was thought to be

malignant and the patient was extremely feeble choledochotomy was not performed, but the gall-bladder was connected to the duodenum by a Murphy's button in order to give temporary relief to the jaundice, fever, and pain. He had a severe rigor on the night of operation but afterwards progressed satisfactorily and recovered from the operation. The button passed on the twelfth day and as he had gained some weight and was taking his food well it was thought that the operation was going to be of real benefit to him. The subsequent history of the case was as follows:—On Dec. 8th (a month and a day after operation) he had a feeling of chilliness, and a temperature of 101° F. followed for two days, his temperature being afterwards normal for 12 days, when he had a rigor and a return of the jaundice; from this time, although he got up every day, he gradually became weaker, and in January, 1900, he developed bronchitis which ushered in the final scene. At the post-mortem examination the peritoneum was found to be free from inflammation and the gall-bladder was found to be connected to the duodenum one and a half inches beyond the pylorus, but the opening had contracted so that it would only admit a fine probe. The common bile-duct was dilated and ulcerated and it contained a gall-stone of the size of a filbert. The liver was considerably enlarged and the right lobe was occupied by an abscess containing thick, slimy mucc-pus. The walls of the abscess cavity were ragged and ill defined and it reached nearly to the surface both in front and behind. It was doubtless the result of the suppurative cholangitis which was present. The pancreas was much indurated about the head, and together with the indurated tissues in the small omentum presented on palpation the sensation of a tumour. On section it presented to the naked eye the appearance of chronic inflammation rather than growth, and on microscopical examination this view was confirmed, there being a great excess of interstitial fibrous tissue, but no sign of cancer.

To add other cases would be tedious to my hearers, but I thought it desirable in bringing forward a subject of this kind to illustrate it by a detailed history of cases that had actually come under my observation. The last case where death occurred from other causes two months after operation is, I think, of importance, as it enabled one to ascertain the after condition of the pancreas which at the time of operation presented the appearance and feel of a considerable tumour. It clearly shows that drainage is capable of relieving the form of pancreatitis which I have described, but that for permanent relief a cholecystotomy is a much safer means than a cholecyst-enterostomy, seeing that the fistula in the latter operation may close before it has completely done its work.

The difference in the results of operations for chronic pancreatitis and cancer of the pancreas is well shown in my own practice. Of 17 patients on whom I have operated and found chronic pancreatitis to be the obvious disease present, 16 have recovered, and except in the one case related the patients have been restored to health; whereas in cancer of the pancreas, of 16 patients only nine recovered from the operation and of these the prolongation of life was so short as to make me reiterate what I said years ago that if we can diagnose cancer of the pancreas with certainty any operative treatment is likely to be useless or harmful. Seeing, however, that sometimes the diagnosis may be doubtful, and that this must often be the case in young and middle-aged subjects, I am of opinion that an exploratory operation should be seriously considered in such cases, as, should the case turn out to be an inflammatory condition of the pancreas and not cancer, I think that I have proved that much may be hoped for by surgical treatment.

WESTERN COUNTIES VETERINARY ASSOCIATION.—The half-yearly meeting of this association was held at Plymouth on July 19th under the presidency of Mr. P. G. Bond. The President, in the course of an interesting address, reviewed the condition of the veterinary art for the past 30 years. Mr. Bond, in referring to the war in South Africa, said that anyone reading of the frightful condition of the horses and their want of proper treatment, as testified to by expert evidence, must be impressed with the urgent need of the veterinary department of the army being put on a proper footing, and he added that until the position of the veterinary surgeon in the army was as fully recognised as that of the medical officer, so long would this lamentable state of affairs continue.

A Clinical Lecture

ON

HAMMER-TOE AND HALLUX VALGUS AND RIGIDUS.

Delivered at St. George's Hospital on Jan. 23rd, 1900,

BY WARRINGTON HAWARD, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE HOSPITAL.

GENTLEMEN,—There were three cases of "hammer-toe" admitted last week under my care; and so with these illustrations available, I think that it may be useful to make this deformity the subject of to-day's lecture. The cases may not seem at first sight to be of much importance or interest, and yet the condition is well worthy of your attention because of its frequent occurrence and the inconvenience which it produces. In its advanced or neglected stages the condition gives rise to painful and disabling lameness, and may thus prevent the sufferer from earning his living; or by interfering with exercise it may lead to serious loss of health.

The deformity to which the name of "hammer-toe" is applied consists of a retraction of the toe towards the metatarsus, with flexion at the first interphalangeal joint. An examination of cases in the early stages shows that the deformity commences by the retraction or hyper-extension of the proximal phalanx. The extensor tendon can be seen and felt on the dorsal surface of the toe, firmly contracted and showing prominently beneath the skin over the metatarsal bone. After a time, and as the retraction becomes more pronounced, the second phalanx becomes flexed so as to bring the last phalanx to the ground. This position throws undue pressure upon the extremity of the ungual phalanx, which is thrust upwards and extended upon the second phalanx, and the skin of the tip of the toe becomes greatly thickened and hardened. When this stage is reached the first interphalangeal knuckle projects prominently above the level of the adjacent toes; and now there is developed over the joint a corn which is the chief cause of the pain and lameness which ensue. Beneath the hard and thickened skin of all corns there is developed a bursa, the inflammation of which gives rise to the lancinating pain so often suffered. The outer wall of this bursa is continuous with the subcutaneous connective tissue, and hence, when the bursa becomes inflamed or suppurates, it very easily becomes the starting-point of a cellulitis which may spread up the limb and reach a serious degree and extension. This is especially the case when suppuration occurs within the bursa; the density of the surrounding tissues makes it difficult for the contained pus to escape, and I have seen many a serious case of cellulitis of the foot and leg having this origin. Short of this severe complication, however, the corn over the hammer-toe is certain to be the seat of frequently recurring inflammation, giving rise to severe pain and completely preventing walking, until at last ulceration occurs and causes persistent lameness and misery. So, you see, may an apparently trivial deformity become of serious and far-reaching importance.

I exhibit to you a number of specimens of hammer-toe which I have added to our museum, and which have been prepared to show the pathological anatomy of the condition. Some have been dissected to display the tendons and ligaments, and others to demonstrate the corn and subjacent bursa; in others sections have been made that the changes of the shape and position of the bones may be seen. I have dissected a great many such toes and have found them all showing essentially the same character. A study of the specimens before you will show the following points of interest besides those which I have already described. 1. That the deformity is not, as has sometimes been stated, dependent upon contraction of the *flexor*. It is not a mere flexion of the phalanx, but something quite different and more complex—viz., a hyperextension of the proximal phalanx, a flexion of the second phalanx, and a thrusting upwards and hyperextension of the ungual phalanx. 2. The extensor tendon is shortened; the flexor is not contracted but follows the plantar retiring angle. 3. The lateral ligaments

are shortened, the plantar ligaments are unaltered. 4. The articular surface of the first and second interphalangeal joints are altered in shape in accordance with the incidence of the pressure caused by their fixation in an abnormal position.

A clinical examination of the cases in the hospital shows in each case a condition of the toe exactly corresponding with the specimens upon the table. In each case it is the second toe which is affected, and all the specimens which I have shown you are second toes. Of the three patients before us Case 1 is that of a boy, aged 12 years, who has been lamed for several months owing to the inflammation of the corn on the hammer-toe. The second toe of the right foot presented the usual characters of the deformity—the first interphalangeal knuckle projected above the first and third toes, the corn over it was swollen, and the surrounding skin was red and tender. He tells us that several of his uncles have a similar condition of the toes, but he cannot furnish precise details of them. The boy is anxious to obtain employment in the public service, and therefore he desired a cure without amputation of the toe After subduing the inflammation of the corn I excised the articular surface of the proximal phalanx together with the corn, dividing at the same time the extensor tension, and at once straightened the toe.

Case 2 is that of a man, aged 23 years, who for the past year has been constantly lamed by the inflammation of the corns over a hammer-toe on each foot. The second toes had been contracted as long as he could remember and had gradually become more troublesome. He wished to have the toes amputated, and this has been done, the toes being removed by the oval method at the metatarso-phalangeal joint. I show you these toes, one of which has been dissected to exhibit the tendons and ligaments. The other has been sawn through longitudinally to display the position of the bones.

Case 3 is that of a domestic servant, aged 19 years, in whom the second toe of the right foot was a well-marked "hammer-toe." The toe has been contracted since early childhood, and lately the frequent recurrence of inflammation of the corn over the interphalangeal joint has been a constant source of lameness. Besides this the great toe was thrust outwards and its last phalanx pressed against the third toe, causing ingrowing of the toe-nail. The corn over the hammer-toe was ulcerated and the ungual phalanx was very bulbous with much thickening of the skin of the end of the toe, and of the nail. At the patient's urgent request I amputated the toe. At the same time I cut away the granulations and a circular flap of skin on the outer side of the nail of the first toe; by the contraction of the resulting cicatrix the skin was drawn away from the edge of the nail and its ingrowth prevented. The patient will wear a wedge of felt between the first and third toes, and must take care to have boots with a straight inner edge.

As to the causes of this deformity I must admit that I have no satisfactory explanation. It is not usually caused, as so many deformities of the foot are, by wearing mis-shapen boots, although it is occasionally attributable to the use of narrow boots, whereby the toes being crowded together the second toe is thrust up above the level of the adjacent toes. I have also seen a few instances in which I thought that it might have been caused by too short boots. In many cases the tendency to hammer-toe is inherited, the deformity often appearing in one side only of the family. In Case 1 several of the boy's uncles were said to possess hammer-toes. In the forty-fourth volume of the Transactions of the Pathological Society of London I have published a case which well illustrates this heredity.

The patient was a boy, aged 15 years, in whom the second toe of the right foot was a hammer-toe. His paternal grandmother (A) had hammer-toe—viz., the second toe of the right foot. A's son (B), the father of the patient, had the same condition of the second toe of the right foot. The following are particulars regarding B's children:—(1) son, hammer-toe, second toe of the right foot; (2) daughter, hammer-toe, second toes of both feet; (3) daughter, no deformity; (4) daughter, no deformity; (5) son, hammer-toe, second toe of the left foot; (6) daughter, no deformity; and (7) son, hammer-toe, second toe of the right foot.

The condition is sometimes congenital and may be seen in various degrees in infants. A somewhat similar condition of the fifth toe also occurs in infants. This is always congenital and does not as a rule attain the same degree of severity as in the second toe.

Then there is another class of cases in which all or nearly all the toes acquire a similar distortion, not usually of very severe degree, but sufficient to cause a very awkward gait and often considerable lameness. These are mostly met with in neurotic girls with bad circulation, whose toes are blue and cold, and in whom the first symptom is aching pain with contraction of the common extensor of the toes. After a time, as retraction of the first phalanx occurs, a proportionate amount of flexion of the toes is seen and corns begin to form over the knuckles. These differ from the ordinary cases of hammer-toe in several respects. In the first place all the toes are affected, as contrasted with the ordinary cases in which only one toe is contracted. Then, secondly, the deformity does not usually attain so severe a degree as in the ordinary form. And thirdly, when the patient is at rest the toes can be to a great extent straightened, though they are drawn into the contracted position immediately when movement is attempted. To which it may be added that this form of the deformity though not confined to women is very much more common in them; whereas the ordinary form is more prevalent among men. These cases seem to be of nervous origin, they prevail chiefly among overgrown, ill-nourished young women of feeble muscular power and constipated habit, who usually exhibit other signs of nerve disturbance.

Coming now to the consideration of the treatment of hammer-toe, I will speak first of the class of cases just described in which all the toes are affected. For these, in the early stages, manipulation of the muscles, friction of the limb and tip-toe exercise should be used; in addition to which attention should be paid to the general condition of the health. These patients should be warmly clothed, should be given plenty of fatty food, and should be treated for any tendency to constipation. Any cause of nervous irritation should be sought for and if possible removed, and every effort should be made to improve the nutrition of the body. If the extensor tendons are persistently contracted they should be divided. Moderate exercise, stopping short of fatigue, is beneficial, and the more varied such exercise the better is its effect. Active games, therefore, such as tennis and hockey, should be encouraged. Of course, properly-shaped boots with straight inner edge, broad soles, and low heels should be insisted upon. In the cases occurring in infants, much may be done by daily stretching and manipulation of the toe, together with, in some cases, division of the extensor tendon and any contracted ligamentous bands.

For the ordinary and pronounced cases of hammer-toe, such as those now in the hospital, there are several methods of successful treatment which may be adopted. The quickest way of ridding the patient of the trouble of a severe degree of hammer-toe is to amputate the affected toe at the metatarso-phalangeal joint by the oval incision, so that there is no scar on the plantar surface. The head of the metatarsal bone should be left, and the patient should be directed to wear a wedge of felt between the first and second toes to keep them apart and to prevent eversion of the great toe. Many hospital patients, naturally anxious for the quickest possible cure, prefer thus to sacrifice the toe rather than to submit to any of the conservative methods of treatment. But it is undesirable and unnecessary as a rule to remove the toe, especially in those persons why are destined for the public services, and the deformity may be easily and successfully remedied by excising the head of the proximal phalanx. This is best done be turning back a semilunar flap from the dorsum of the too and dividing the lateral ligaments; the head of the bone is then thrust out of the wound and cut off by bone forceps. If there is a bad corn over the knuckle it is best to excise it completely by converting the semilunar into an oval incision which surrounds the corn. The toe is then straightened, the skin is united by sutures, and the foot is kept on a splint for three weeks. Fibrous union occurs between the bones and the toe remains straight and gives no further trouble. Patients thus treated are quite fit for active service in the army.

In early cases of less severity, and in which there is no pronounced corn, it may suffice to divide the extensor tendon and the lateral ligaments, together with any bands that prevent complete straightening of the toe, and then to fix the toe for some weeks upon a narrow splint. This operation and the subsequent use of manipulation and stretching of the toe will cure many of the cases met with in children; but severer cases are much more successfully treated by excision of the head

of the first phalanx. Should the patient seek advice, as often happens, on account of acute inflammation of the corn over a hammer-toe, it will of course be wise to subdue this before undertaking any operation for the relief of the deformity. Let me remind you that when there are redness and œdema of the skin round an inflamed corn these symptoms and the accompanying pain depend upon inflammation and distension of the little bursa between the corn and the bone; and that speedy relief may be given by opening the bursa by passing a knife beneath the margin of the corn towards its centre and raising the thickened cuticle so that the fluid contained within the bursa may escape. A hot boric fomentation should then be applied, and when the bursitis and consequent cellulitis have completely subsided the excision of the corn, together with the head of the first phalanx, should be undertaken. Of the many cases in which I have practised this simple operation I have never seen other than a satisfactory result.

Besides these cases of hammer-toe you have recently seen under treatment a case of severe bunion, or "hallux valgus," on which it may be useful to say a few words; for this, again, is a common deformity which often gives rise to great suffering.
